homology was found in residues 3–7 in cerropin A (Lys-Leu-Phe-Lys-Lys)—these are identical to residues 40–44 in the major coat protein of the filamentous phages fd and fl (ref. 11). Homology was also found in residues 25–28 (Ala-Val-Ala-Val) which are also present in the signal peptide of the λ receptor protein 12. It is possible that these two sequences could be involved in the membrane-crossing activities of the respective proteins.

Third, the amino acid composition and size of the cecropins are different from those of the bactericidal and basic proteins in polymorphonuclear leukocytes¹³ and from the antibacterial factors in seminal fluid¹⁴, saliva¹⁵ and milk¹⁶. Thus we conclude that cecropins A and B differ from other known antibacterial proteins. Similar compounds have been found in many other Lepidoptera¹⁷ and we suggest that the name-cecropin should be applied to all antibacterial proteins which show a substantial homology with cecropins A and B.

We have previously shown that cecropins kill and lyse Escherichia coli and some other bacteria⁷. Using other methods we have now compared the biological activity of the cecropins with the bee venom toxin melittin (for a review see ref. 9). The nature of these two molecules is essentially similar; they are both small polypeptides with one part of the chain being strongly basic and one part predominantly hydrophobic. However, the C-terminal in melittin is basic, whereas it is the N-terminal that is basic in the cecropins.

The antibacterial effects of haemolymph, lysozyme, melittin and cecropins A and B were tested on six different bacteria (see Table 2). Activity against all organisms tested was induced in the haemolymph by vaccination with Enterobacter cloacae. Both cecropins had similar antibacterial spectra, although the B-form was significantly more active against Bacillus subtilis. Melittin showed no antibacterial activity against Serratia marcescens and Xenorhabdus nematophilus and for the remaining bacteria it had a lower activity than the cecropins. Differences in activity against the various organisms in Table 2 must be interpreted with care as some of the bacteria can produce proteolytic exoenzymes.

Figure 2 shows the bactericidal and lytic activities of cecropin A and melittin on $E.\ coli$ D31 and on Chang liver cells. Melittin has a high lytic activity against both $E.\ coli$ and the Chang liver cells whereas cecropin A was specific for the bacterial cells. Even at concentrations as high as 20 μ M there was no detectable effect on the Chang liver cells, while a 300 times lower concentration gave 50% lysis of $E.\ coli$. The specificity of the cecropins agrees with earlier findings³ that immune haemolymph has no effect on sheep erythrocytes or insect tissue culture cells (unpublished data).

We have drawn two conclusions from our experiments. First, that the eccropins are the main antibacterial components so far identified in immune haemolymph which act against potential insect pathogens like S. marcescens, Pseudomonas aeruginosa

 Table 2
 Antibacterial activities of lysozyme, cecropins A and B and melittin

Organism		Diame			eter of inhibition	zone (mm)	Water and the second se			
	Strain	NH	IH	Lysozyme	Cecropin A	Cecropin B	Melittin	Blank		
E. coli K12	D31	2.7*	13.2	2.7*	14.0	12.5	7.6	2.7*		
S. marcescens	Db1108	2.7*	6.2	2.7*	7.6	7.2	2.7*	2.7*

B. subtilis	Bs11		5.2		2.7*	7.2				

Antibacterial activity was recorded as inhibition zones on thin agar plates of a rich medium plus $\sim 8 \times 10^4$ viable cells per 6 mi. As all strains are streptomycin resistant, all the plates contained streptomycin (100 μ g ml⁻¹). The concentration of cecropins A and B and melittin was 0.13 mM in all cases except the last two, where the cecropin concentration was 0.55 mM. The concentration of the cecropia lysozyme was 0.03 mM. The volume applied to each well was 3 μ l. Normal haemolymph (NH), immune haemolymph (IH) and a blank with 0.4 M ammonium formate buffer were used as references. IH, lysozyme and the cecropins were prepared as described in Fig. 1 legend. The diameter of the inhibition zones is proportional to the log of the concentration of inhibiting agent¹⁷. Well diameter 2.7 mm.

^{*} No inhibition was detected.

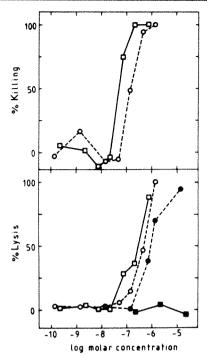

Fig. 2 Comparison of the action of cecropin A (squares) with melittin (circles) on E. coli D31 (open symbols) and Chang liver cells (closed symbols). E. coli (10⁸ viable cells per ml) was incubated with the bacteriolytic agent at 37 °C in 0.1 M phosphate buffer, pH 6.4. After 30 min the tubes were put on ice and samples were withdrawn and diluted for viable count (given as per cent killing in the upper part of the figure). The remaining incubation mixture was centrifuged, and A260 of the supernatant was measured. Lysis is given as per cent of maximum release, corrected for the spontaneous release in buffer alone. Growth of strain D31 and other details were as before⁷. Chang liver cells were cultured in Parker 199 medium containing 5% fetal calf serum (FCS). The cells were washed and labelled with Na₂⁵¹ CrO₄ (0.1 mCi ml⁻¹) at 37 °C for 1 h in a Tris-Hanks buffered solution containing 3% FCS. The monolayer was then trypsinated and washed (R. Alsheikhly, in preparation). The lytic agent was added to 10⁵ cells in 0.1 ml Tris-Hanks medium. The percentage of ⁵¹Cr in the supernatant was measured after a 2-h incubation at 37 °C.

and X. nematophilus. A comparative study 17 which included the greater wax moth, Galleria mellonella, and seven other Lepidoptera showed that cecropin-like substances are widely distributed in this order. As lysozyme is bactericidal for only a limited number of Gram-positive bacteria we believe that its main function is to remove the debris remaining after lysis of bacteria by cecropin.

Second, the cecropins must have a structure that prevents attack on the insect itself. This structural information is presumably absent in melittin; bees avoid self destruction by synthesizing an inactive precursor which is activated by a sequential liberation of dipeptides18. Future studies of the sequences of other cecropins should yield more information about the recognition of self in insects as well as an understanding of the bactericidal mechanism of the cecropins.

We thank Dr. A. R. Alsheikhly for help in the experiments with Chang cells. This work was supported by grants from the Swedish Natural Science Research Council (BU2453 to H.G.B.) and from the Swedish MRC (13P-5057 and 13X-3556 to H.B.).

Is membrane expansion relevant to anaesthesia?

N. P. Franks

General anaesthesia can be induced by a wide variety of structurally dissimilar molecules. Consequently, the mechanism must involve some rather nonspecific interactions at the target site, generally held to be in nerve membranes. The primary site of action has been postulated to be either lipid or protein or both. Although recent work 1-4 has cast doubt on the lipid hypotheses, protein models still flourish. In particular, Seeman and his co-workers⁵⁻⁸ have shown that biological membranes expand when anaesthetic molecules are added, and that this expansion is far greater than that which occurs with lipid bilayers. It has been suggested that this difference is due to extensive conformational changes in the membrane proteins, and several mechanisms have been proposed^{6,9,10} to explain this large expansion of proteins. We now report the first direct measurements of the volumes occupied by general anaesthetic molecules in both biological membranes and lipid bilayers. We show that, in fact, biological membranes expand much less and lipid bilayers expand more than previously reported. The volume that a general anaesthetic molecule occupies is essentially the same in biological membranes, lipid bilayers and water. Our results lead us to question all generalized membrane expansion hypotheses for the mechanism of general anaesthesia, in favour of hypotheses which include more specialized target sites.

The approach we used consisted of determining membrane densities and membrane/buffer partition coefficients as a function of anaesthetic concentration. A straightforward and extremely accurate method of measuring solution densities, using a vibrating tube, has been developed by Kratky and co-workers¹¹. Commercially available instruments are capable of measuring densities to an accuracy of about 10^{-6} g cm⁻³ measuring the density $\rho_{\rm sus}$ of a membrane suspension and the density ρ_{buf} of the buffer alone, the density of the membrane can be calculated as

$$\rho_{\text{mem}} = \frac{\rho_{\text{sus}} \, \rho_{\text{buf}}}{\rho_{\text{buf}} - R \, (\rho_{\text{sus}} - \rho_{\text{buf}})} \tag{1}$$

where R is the ratio of buffer mass to membrane mass. (This equation can be derived from the simple relationship v_{mem} + $Rv_{\text{buf}} = (1+R)v_{\text{sus}}$, where v stands for specific volume, the reciprocal of density.) Seeman⁸, using such an instrument, has reported large changes in the density of biological membranes but only very small changes in the density of lipid bilayers due to the presence of ethanol. As some of his data have recently been questioned¹², we began by repeating these measurements.

Our results using ethanol are shown in Fig. 1. The curves in Fig. 1a show the progressive decrease in densities of both buffer and a suspension of human red blood cell membranes, as a

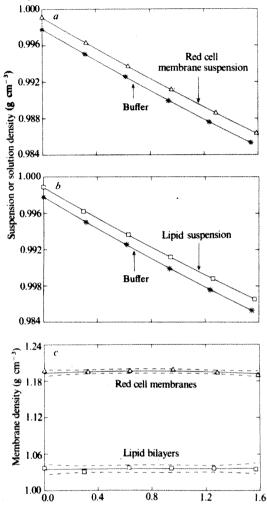

Fig. 1 Membrane density measurements with ethanol. a, Density of human red blood cell membrane suspension (\triangle) and of buffer (*) as a function of the buffer ethanol concentration. b, Density of bovine spinal cord lipid suspension (\square) and of buffer (*) versus buffer ethanol concentration. c, Density of red cell membranes (△) and spinal cord lipid membranes (□) versus buffer ethanol concentration, together with 95% confidence envelopes (dashed lines). Red cell membranes were prepared from transfusion blood (<1 week old) according to the method of Dodge et al. 19. Total spinal cord lipids were especially prepared by Lipid Products Ltd and supplied as a solution in chloroform/methanol. Most of the solvent was removed using a rotary evaporator; remaining traces were removed by pumping under high vacuum for 6 h. The dry lipids were dispersed in buffer by vortex action and brief immersion in a sonicating bath. The buffer used in all our experiments was 5 mM potassium phosphate (pH 8). Precise values for ethanol concentrations were obtained using $c = c_{\rm stk}(M_{\rm stk}/M)(\rho/\rho_{\rm stk})$, where c, M and ρ were the ethanol concentration, the mass and the density, respectively, of the final solution or suspension, and $c_{\rm stk}$, $M_{\rm stk}$ and $\rho_{\rm stk}$ were the corresponding quantities for stock solutions of ethanol in buffer, which were added to membrane suspensions or buffer. For the red cell suspension, a small correction (always <1%) in c was made for partitioning of ethanol into the membranes, using a value of 0.14 moles ethanol per kg membrane/moles ethanol per I buffer. To determine membrane weights, dry weights of the membrane suspensions were measured gravimetrically and corrected for buffer salt weight. The value of R (=buffer weight/membrane weight) for the red cell membrane suspensions was 126.6 ± 2.5 , and 33.33 ± 0.39 for the spinal cord lipid suspension; the errors are for 95% confidence limits. All density measurements were performed using a precision density meter (Anton Paar, Model DMA O2C) at 25 °C. Temperature was maintained constant to within ± 0.01 °C. The curves in a and b were fitted to quadratics using the method of least squares. The curves and data points in c were calculated from the appropriate curves and data points of a and b using equation (1). The 95% confidence envelopes were calculated by least squares fitting of the data points to a quadratic

1.2

Buffer ethanol concentration (M)

04

function of the ethanol concentration in the buffer. Figure 1b gives the analogous results using bovine spinal cord lipids. Finally, Fig. 1c shows red cell membrane and spinal cord lipid densities, together with 95% confidence envelopes, as a function of the buffer ethanol concentration.

The most obvious feature of Fig. 1c is the clear difference in density between red cell and lipid membranes, due, of course, to the fact that red cell membranes contain about 50% protein. More important in the present context is the fact that, as regards the change in density with ethanol concentration, there is no significant difference between red cell membranes and spinal cord lipids. Indeed, there is no significant change in the density of either membrane over the range of ethanol concentrations we used. Our data are in direct disagreement with the experimental results reported by Seeman⁸, which showed a large (5%) change in red cell membrane density over the same range of ethanol concentrations.

It is important to appreciate that there is no simple relationship between changes in membrane density and changes in membrane volume. For example, if an anaesthetic has the same density in a membrane as the membrane itself, large expansions of membrane volume could occur without any change in density. The change in membrane volume can be calculated if one knows the partial molar volume, \bar{V}_{an} , of the anaesthetic as a function of its membrane concentration c_{mem} . \vec{V}_{an} , which has units of volume per mol, represents the change in membrane volume per mol of anaesthetic at a given anaesthetic concentration. The partial molar volume is directly related to changes in membrane density by the expression¹

$$\bar{V}_{\rm an} = \frac{M_{\rm an} - (\partial \rho_{\rm mem} / \partial c_{\rm mem})}{\rho_{\rm mem} - c_{\rm mem} (\partial \rho_{\rm mem} / \partial c_{\rm mem})} \tag{2}$$

where $M_{\rm an}$ is the molecular weight of the anaesthetic, and $\rho_{\rm mem}$ is the membrane density at an anaesthetic molar concentration in the membrane of c_{mem} . If the membrane density is observed to change linearly with concentration, that is, if ρ_{mem} = $\rho_{\text{mem}}^0 + mc_{\text{mem}}$, then equation (2) reduces to

$$\bar{\mathbf{V}}_{\rm an} = (\mathbf{M}_{\rm an} - \mathbf{m})/\rho_{\rm mem}^{0} \tag{3}$$

where m is the slope of the curve of membrane density versus c_{mem} , and ρ_{mem}^0 is the membrane density in the absence of anaesthetic. Using this equation and the red cell membrane data from Fig. 1c, and taking a membrane/buffer partition coefficient of 0.14, $\bar{V}_{\rm an}$ for ethanol lies between 20 and 65 cm³ mol^{-1} , with 95% confidence. Furthermore, the mean \vec{V}_{an} for ethanol in the spinal cord lipids also falls within this range. Now, the partial molar volume of ethanol in buffer, calculated directly from the buffer density data of Fig. 1a,b, varies between 53.5 and 55.1 cm³ mol⁻¹ over the ethanol concentrations used. Thus, there seems to be no dramatic difference in the volume that an ethanol molecule occupies in red cell membranes, lipid bilayers and water.

However, ethanol is not the best choice of anaesthetic molecule if one is interested in measuring partial molar volumes in membranes. This is because, being relatively polar, ethanol has a small membrane/buffer partition coefficient Consequently, only indirect and uncertain estimates of K exist or can be easily obtained. Furthermore, ethanol is not an anaesthetic which is used clinically. We therefore repeated our density measurements using the apolar anaesthetic halothane (Fig. 2) which is both widely used clinically and for which we were able to measure accurate membrane/buffer partition coefficients as a function of anaesthetic concentration. Note that the solution and suspension densities all increase with halothane concentration, whereas the opposite behaviour (decreasing density) was seen with ethanol concentrations (see Fig. 1). This, of course, reflects the fact that liquid halothane ($\rho = 1.87 \, \mathrm{g \ cm^{-3}}$) is much denser than membranes and buffer, whereas ethanol ($\rho = 0.79 \text{ g cm}^{-3}$) is less dense. Figure 2c shows the red cell membrane and spinal cord lipid densities (with 95% confidence envelopes), calculated using the data from Fig. 2a, b and equation (1).

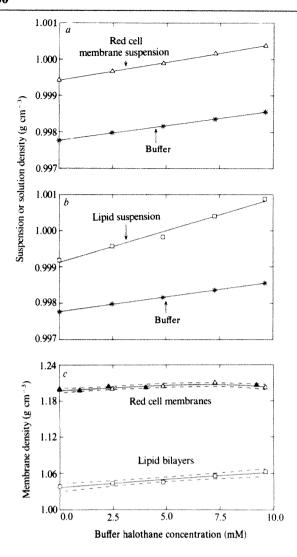

Fig. 2 Membrane density measurements with halothane. a, Density of human red blood cell membrane suspension (\triangle) and of buffer (*) as a function of the buffer halothane concentration. b, Density of bovine spinal cord lipid suspension () and of buffer (*) versus buffer halothane concen tration. c, Density of red cell membranes (\triangle and \blacktriangle) and spinal cord lipid membranes ([]) versus buffer halothane concentration, together with 95% confidence envelopes (dashed lines). The membrane suspensions were prepared and the density measurements performed as described in Fig. 1 legend. Known partial pressures3 of halothane in nitrogen were bubbled through the buffer and then passed over the membrane suspension, which was contained in a small (5 ml) round-bottomed flask. The suspension was stirred, using a glass-encapsulated magnetic 'flea'. This had the important technical advantage that the buffer concentrations of anaesthetic in equilibrium with the membranes was known directly and did not have to be corrected for partitioning into the membranes. The equilibrium concentration of halothane in the buffer and the aqueous phase of the membrane suspension was calculated² using an Ostwald solubility (water/gas partition) coefficient²⁰ of $\lambda = 1.5$ (at 25 °C). To avoid loss of halothane to air, the solutions were directly transferred to the density meter in a syringe containing no air pockets. The value of R (= buffer weight/membrane weight) was corrected for the differential partitioning of halothane between membranes and buffer using $R = R_0(1+M_{\rm an}c_{\rm buf}/\rho_{\rm buf}^0)/(1+M_{\rm an}Kc_{\rm buf}/\rho_{\rm mem}^0)$, where R_0 is the value of R when $c_{\rm buf}=0$. R_0 was $100.0\pm1.9~(\triangle)$, $74.3\pm3.4(\triangle)$ and 26.55±0.24 (□); the errors are for 95% confidence limits. Partition 20.33 ± 0.24 (a), the errors are 10 ± 9.3 confidence limits. Farthful coefficients K (=moles halothane per l membrane divided by moles halothane per l buffer) were determined using 14 C-labelled halothane (NEN) and equilibrium dialysis at 25 °C. The labelled halothane was repeatedly washed with buffer until its halothane/buffer partition coefficient was constant and consistent with its known solubility in water. For the red cell membrane determinations, SDS-polyacrylamide gels run before and after dialysis showed that no significant hydrolysis of membrane proteins had occurred. The measurements were performed as a function of aqueous concentration of halothane from zero to about 8 mM and fitted to least-squares polynominal curves of the statistically appropriate order²¹. The results were $K = 29.5 + 0.84c_{\text{but}}$ for spinal cord lipids and $K = 38.4 - 5.24c_{\text{but}} + 0.770c_{\text{bu}}^2$ for red cell membranes, where $c_{\rm buf}$ has units of moles halothane per l buffer. The density curves in a and b were fitted to straight lines using the method of least squares, and the curves and data points (\triangle, \Box) in c were calculated from the appropriate curves and data points of a and b using equation (1). The additional data points (\triangle) in c are the results from a completely independent red cell membrane experiment and give a measure of the reproducibility of the data. For the red cell membranes two data points are superimposed at zero halothane concentration. The 95% confidence envelopes were calculated by least-squares fitting of the data points.

The data in Fig. 2c clearly show that there is a significant increase in the densities of both red cell membranes and lipid bilayers with increasing halothane concentration (except in the very highest concentration range for red cell membranes—see later). Accurate values of the partial molar volumes $\bar{V}_{\rm an}$ can be obtained using these data if the concentrations of the anaesthetic in the membranes are known. To convert buffer concentrations to membrane concentrations, the partition coefficient K (mols halothane per I membrane divided by mols halothane per I buffer at equilibrium) had to be determined. We measured K as a function of halothane concentration for both red cell and lipid membranes, using equilibrium dialysis and 14C-labelled halothane. Combining these results with the density measurements shown in Fig. 2c, we could calculate membrane density as a function of membrane halothane concentration (Fig. 3). The relationships between membrane density and membrane halothane concentration do not differ significantly from straight lines up to about 300 mM. Therefore, we could calculate $\bar{V}_{\rm an}$ in this range using equation (3), for both red cell and lipid bilayer membranes. Using equation (3) with $M_{an} = 197.4 \text{ g mol}^{-1}$ and taking m and ρ_{mem}^0 as the slopes and intercepts of the least squares lines of Fig. 3, the values ($\pm 95\%$ confidence limits) are $V_{\rm an} = 134 \pm 14 \, {\rm cm}^3 \, {\rm mol}^{-1}$ for human red blood cell membranes and $\vec{V}_{an} = 124 \pm 24 \text{ cm}^3 \text{ mol}^{-1}$ for bovine spinal cord lipids. Thus, there is no significant difference between the partial molar volume of halothane in red cell and lipid membranes. It follows that, at equal membrane concentrations, halothane expands both membranes by the same amount. Furthermore, $ar{V}_{
m an}$ in these membranes is about the same as it is in buffer $(116.7 \pm 3.2 \text{ cm}^3 \text{ mol}^{-1} \text{ at } 95\% \text{ confidence, calculated using the})$ buffer data of Fig. 2).

Our results using halothane thus provide a firm quantitative basis for the conclusions which could be drawn from our experiments with ethanol. We find virtually no difference in the volume that a given anaesthetic molecule occupies in biological membranes, lipid bilayers or water. This was true for both halothane and ethanol, two very different general anaesthetics. We should point out that the range of anaesthetic concentrations used in our experiments included not only general anaesthetic but also nerve blocking levels.

Our measurements throw new light on membrane expansion theories of anaesthesia. These theories have the attraction of providing a conceptually simple framework for understanding the phenomenon of pressure reversal of general anaesthesia. The most popular of these, the critical volume hypothesis, states¹⁴ that "Anaesthesia occurs when the volume of a hydrophobic region is caused to expand beyond a certain critical amount by the absorption of molecules of an inert substance. If the volume of this hydrophobic region can be restored by changes of temperature or pressure, then the anaesthesia will be removed." At concentrations of halothane that produce general anaesthesia in man ($c_{\text{buf}} = 0.27 \text{ mM}$), the expansion $(\bar{V}_{\rm an}c_{\rm mem})$ calculated from the data of Fig. 3 for both membranes and bilayers is only about 0.1%. This observed expansion is very small, in view of recent measurements¹⁵ which show that cholesterol-containing lipid bilayers expand by about 0.1% per °C. Thus, were the critical volume theory to be applied to whole membranes, it would predict that a rise in temperature of only a few degrees should induce general anaesthesia. This is not observed in cold-blooded animals. (A similar line of reasoning^{2-4,16,17} has been used to discredit both lipid phase transition models and bilayer fluidization hypotheses of anaesthesia.)

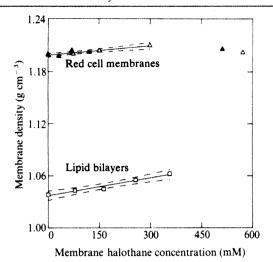

Fig. 3 Membrane density as a function of membrane halothane concentration and the determination of the partial molar volume \vec{V}_{an} for human red cell membranes (upper line) and bovine spinal cord lipids (lower line). The slope and intercept of each least-squares straight line was used to calculate \tilde{V}_{nn} with equation (3); the 95% confidence limits were calculated using these values and the variance—covariance matrix²². The red cell data points above 500 mM, where we suspect that some protein denaturation had occurred²³, were not included in the analysis. For red cell membranes, $134 \pm 14 \text{ cm}^3 \text{ mol}^{-1}$; for lipid bilayers, $\overline{V}_{an} = 124 \pm 24 \text{ cm}^3 \text{ mol}^{-1}$

Furthermore, our observation that the volume occupied by a halothane molecule is essentially the same in membranes, water and liquid halothane shows that although membranes do indeed expand, the expansion is almost wholly accounted for by the volume of the halothane molecules themselves and does not, as previously thought⁸ for biological membranes, involve the creation of a large additional free volume which might then be compressed by the application of high pressures.

Overall, we conclude that the expansion of whole membranes or lipid bilayers is not relevant to the mechanism of anaesthesia. On the other hand, our results are consistent with the idea that general anaesthesia is caused by interactions with specialized regions of nerve membranes, which have properties quite different from those we have measured for whole membranes. Indeed, the partial molar volume of an anaesthetic molecule in these regions may well be much larger than in the rest of the membrane or in water; pressure reversal could then be simply a consequence of forcing the anaesthetic away from its target¹⁸ We have previously shown^{2,3}, using X-ray and neutron diffraction, that lipid bilayer structure is not significantly affected by general anaesthetics at up to 10 times clinical concentrations. Thus, it seems unlikely that general anaesthesia involves any sizeable structural change in the lipids of such specialized regions. This leaves us to suppose that it is the structure of particularly sensitive membrane proteins which are directly affected. For example, it could be that the target site is a multisubunit protein immersed in the membrane and that anaesthetics interfere with its function by interposing themselves between the subunits and disrupting the packing. The fact that general anaesthesia can be induced by a wide variety of structurally dissimilar molecules, whereas most drug/receptor interactions are rather specific, follows directly from such an idea. (A specific key is necessary to unlock a door, but anything can be used to prevent it from closing.)

We thank Dr E. G. Richards for stimulating discussions throughout this work, Dr W. B. Gratzer for help with the equilibrium dialysis measurements, Mr V. Ohanian for running the polyacrylamide gels, and Professor D. M. Blow for helpful comments on the manuscript. This research was supported by a project grant from the MRC and by a grant from the British Oxygen Corporation Limited.

Fast inward and outward current channels in a non-spiking neurone

Maurizio Mirolli*

Békésy Laboratory of Neurobiology, 1993 East-West Road, University of Hawaii, Honolulu, Hawaii 96822, USA

Although the crustacean coxal receptors are non-spiking2.3, indirect pharmacological and electrophysiological evidence suggests that fast sodium channels may be present in their membrane⁴⁻⁶. The properties of these channels are not known, but it has been suggested that they might be "incompletely differentiated", perhaps lacking "appropriate gating mechanisms", and/or "too sparsely distributed". The former hypothesis is not supported by the results of voltage-clamping experiments done on dendritic segments isolated from these mechanoreceptors. Instead, the results reported here provide direct evidence for a voltage-dependent fast inward current, sensitive to tetrodotoxin (TTX) and requiring external sodium (but not calcium). This current is shunted by a transient fast outward current, also voltage dependent, and it is suggested that this shunting may account, at least in part, for the non-spiking behaviour of the coxal receptors.

The largest dendrite (T fibre 1) among those supplying the coxal muscle receptor organ in the crab Portunus sanguinolentus (Herbst) was ligated close to its sensory endings and to its entry into the thoracic ganglion, and then cut distal and proximal to the two ligatures. The input properties of the isolated dendrite were similar to those of intact coxal receptors3. In nine experiments the average and standard deviation of the resting potential were 63.8 ± 5.5 mV and those of the input resistance were $2.2 \pm 1.5 \,\mathrm{M}\Omega$. The current-voltage relationship was characterized by a pronounced outward-going rectification in the depolarizing quadrant. Depolarization by current pulses did not elicit overshooting action potentials (Fig. 1a).

Dendrites could be clamped at holding potentials close to or considerably more negative (up to -80 mV) than their resting potential for several hours without deterioration of their input properties. Depolarizing and hyperpolarizing clamping voltages of small amplitude resulted in symmetrical clamping currents, but at voltages more positive than about -50 mV, a transient inward current (I_N) became evident (Fig. 1b). Both amplitude and time to peak of I_N depended on the magnitude of the test clamping voltage: the amplitude first increased with larger values of the test voltage and then decreased (Fig. 1b), while the time to peak decreased from 3-5 ms to less than 1 ms with increasing intensity of the test voltages. I_N was also dependent on the holding voltage and was completely inactivated in dendrites held at voltages more positive than -55 mV.

 I_N was sensitive to pharmacological agents known specifically to affect voltage-dependent sodium channels8. It was abolished

^{*} Permanent address: Indiana University, School of Medicine, Medica: Sciences Program, Physiology Section, Myers Hall, Bloomington, Indiana 47405, USA

when TTX in concentrations as low as 10^{-8} M was added to the saline (Fig. 1c, d), and when external sodium was substituted by choline, tetramethyl ammonium or tetraethyl ammonium. By contrast, I_N was not affected by agents known to interfere with calcium currents°. Thus, it was not increased when calcium was substituted by either barium or strontium, nor was it abolished or reduced when cadmium (10^{-4} M), manganese or cobalt (both 5×10^{-3} M) were added to the saline.

Even in TTX, clamping currents were not symmetrical in the hyperpolarizing and depolarizing range except, as noted, for small voltage steps. Instead, depolarizing voltages resulted in early fast outward current transients considerably larger than the capacitative transients obtained with hyperpolarizing tests of equal amplitude (Fig. 1c, d legend). For several criteria the fast outward current behaved in a manner similar to the fast inward current; thus, it could not be demonstrated in dendrites held at potentials more positive than about -45 mV, and its time to

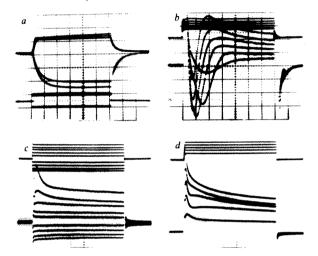

Fig. 1 Example of data obtained by current and voltage clamping in isolated dendritic segments. The preparations, 3-6 mm in length and 80-120 µm in diameter, were pinned to the Sylgard floor of a chamber having an approximate volume of 0.016 ml, and perfused at the rate of about 0.5 ml min⁻¹ with a saline solution of the following molar composition: Na, 0.47; K, 0.01; Ca, 0.026; Mg, 0.052; Cl, 0.513; SO₄, 0.022, buffered to pH 7.6 with 0.005 mol of Na-HEPES. The voltage clamping circuit was modelled after that of Connor and Stevens¹⁰. The current injecting pipette was screened. Position and tip resistance of the two micropipettes used for clamping were critical in obtaining good results. Stable input properties and adequate clamping speed were obtained with pipettes having a resistance of $4-7 \text{ M}\Omega$, inserted in the middle of the dendrites at about 50 µm from each other. Fast clamping was not possible with micropipettes having higher resistance, while the use of micropipettes having lower resistance results in unstable input properties. In each record, voltage is recorded in the top trace and current in the lower one. Calibrations: one major grid division is equal to: a, 20 mV, 50 nA, 50 ms; b, 50 mV, 100 nA, 1 ms; c, 50 mV, 20 nA, 5 ms; d, 100 mV, 50 nA, 10 ms. a, Current clamping of a dendritic segment 5.8 mm long, whose membrane potential (V_m) was -65 mV and input resistance (R_i) 2.2 M Ω . Note lack of spiking activity and pronounced outward-going rectification above -45 mV. b, Voltage clamping of a segment 4.6 mm long $(V_{\rm m}-65~{\rm mV};\,R_{\rm i}\,1.75~{\rm M}\Omega)$. Inward current $(I_{\rm N})$ corresponds to a downward deflection of the current trace. IN reached a maximum value (360 nA) when the segment was depolarized to $-35\,\text{mV}$ from a holding potential of -75 mV. c, d, Outward currents recorded in saline containing tetrodotoxin $(5 \times 10^{-8} \text{ M})$ in a segment 3.6 mm long whose resting potential was -67 mV and input resistance 2.4 MΩ. The preparation was held at -80 mV except during testing. As shown in d, at clamping voltages more positive than -30 mV, the initial outward transient is followed by a second one characterised by a slower rate of decay. This second outward transient is not considered in the text because its time course is too slow to affect the inward current directly. Preliminary results indicate that the slower outward transient can be blocked by external tetraethyl ammonium $(5 \times 10^{-2} \text{ M})$ whereas the initial fast transient is not. Both outward currents are blocked by 4-amino-pyridine $(5 \times 10^{-3} \text{ M})$.

peak decreased with increasing values of the test voltage, from 3-5 ms to <1 ms (Fig. 1c, d). Unlike the inward current, however, the early outward current transient increased monotonically in magnitude with larger values of the clamping voltage (Fig. 1c, d).

The shunting effect of the outward current transients on the inward current flowing through the TTX-sensitive channels can be evaluated from Fig. 2. The difference between clamping currents, recorded in the same preparation in control and in TTX saline, or net inward current, is substantially larger than $I_{\rm N}$ and has a null point at about +50 mV and thus at a voltage close to the reversal potential expected for a sodium current. $I_{\rm N}$, on the other hand, has a null point at about -10 mV, close to the peak values of the partial action potentials which can occasionally be recorded from intact coxal receptors^{3,4}.

The net inward current density, calculated from data such as those presented in Fig. 2, on the assumption that the dendritic segments were properly space clamped, is about $20 \,\mu\text{A} \,\text{cm}^{-2}$ and thus much lower than that measured in excitable membranes. It should be emphasised, however, that the validity of this assumption (as well as other assumptions involved in the

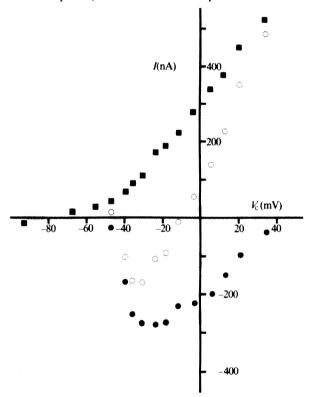

Fig. 2 Plot of clamping currents obtained from the same preparation in control saline (O) and in saline containing TTX () in response to stimuli of equal amplitude (V_c) . Currents were measured at times corresponding to peak amplitude of the inward current in control saline. Their difference, net peak inward current, is plotted (). Clamping was not sufficiently fast at voltages larger than about +15 mV, and therefore no reliable results were obtained close to the null potential of the inward current. By extrapolation, this potential can be seen to be about +50 mV. This dendritic segment was 6 mm long, and its surface was 1.5× 10⁻² cm². As the length constant of the coxal receptor dendrites is at least 3 cm (refs 3, $\overline{7}$) the preparations should have been properly space clamped if the ligatures at their endings were to provide a complete seal¹⁸. On this assumption, peak net inward current density could be calculated to be, in this example, 19 µA cm⁻ Two other experiments yielded values of 18 and 48 µA cm the null potentials were, respectively, +25 and +43 mV. Assuming further that the effective membrane capacitance of the dendrites was about 1 µF cm⁻², the current density thus calculated would be about 10 times lower than that required to charge the membrane to the null potential of the inward current. If the endings were leaky, the amount of membrane under clamp control would have been less, and hence current density would be underestimated by an unknown amount.

calculations) cannot be properly evaluated on the basis of the available data (see Fig. 2 legend). Thus, it seems reasonable to conclude that the inability of the coxal receptor dendrites to develop full action potentials does not depend on a lack of functional sodium channels but rather on the shunting of the sodium current by the transient opening of a fast outward conductance and, possibly, on an abnormally low density of the sodium channels themselves. These two factors are not mutually exclusive; on the contrary, both can be easily interpreted as an expression of the specialization of the coxal receptors for transmitting information with analogue signals^{2,3}

Results consistent with those presented in Figs 1 and 2 were also obtained in the S dendrite of Portunus, as well as in the S and T dendrites of other swimming crabs. Moreover, a fast TTXsensitive and sodium-dependent inward current and a fast initial outward transient could also be demonstrated when clamping intact Portunus coxal receptors. In the intact cells no fast clamping could be obtained at voltages more positive than about -20 mV, and therefore a satisfactory study of the fast currents has not been possible.

The coxal receptors are not unique in exhibiting transiently activated outward currents 10-17. There is convincing evidence that currents of this type are important in regulating repetitive firing of normally spiking neurones 10,14. The early fast outward channels of the coxal receptors, characterised by activation and inactivation rates comparable with those of the inward channels, seem to be specialised for suppressing spiking. Whether this specialisation represents an extreme case of adaptation of membrane components also found in other cells, or whether it reflects unique ionic and pharmacological properties, remains to be determined.

Inhibition of smooth muscle tension by cyclic AMP-dependent protein kinase

W. Glenn L. Kerrick* & Phyllis E. Hoar

Department of Physiology and Biophysics, SJ-40, University of Washington, Seattle, Washington 98195, USA

β-adrenergic relaxation of smooth muscle by catecholamines has been associated with elevated levels of cyclic AMP^{1,2}. The question arises whether subsequent activation of cyclic AMPdependent protein kinase^{3,4} has a role in the regulation of smooth muscle contraction. There is substantial evidence that a Ca²⁺-activated myosin light chain kinase/phosphatase system regulates smooth muscle contraction⁵⁻¹⁵ ', and Adelstein *et* al. 16,17 have shown that the catalytic subunit of cyclic AMPdependent protein kinase^{3,4} plays a part in this regulation, by phosphorylation of the high molecular weight subunit of the light chain kinase, which results in a decrease in the activity of the kinase. Here we have shown for the first time that the catalytic subunit of the protein kinase inhibits Ca2+-activated tension in skinned smooth muscle fibre preparations.

Figure 1a shows that after a submaximal (pCa = 5.0) and a maximal (pCa = 3.6) contraction, addition of 10^{-6} M catalytic subunit of cyclic AMP-dependent protein kinase results in a slow inactivation of the fibres. After transfer of the fibre bundle from this high [Ca²⁺] catalytic subunit solution to a relaxing solution (pCa = 8.0) the fibres relaxed. When they were reimmersed in the same solution (pCa = 5.0) in which they initially gave ~90% maximum tension, they generated only 14% of the subsequent tension in pCa 3.6 solution. This shows that pretreatment with the catalytic subunit of protein kinase resulted in a decrease in the Ca2+-sensitive threshold for contraction of the muscle fibre preparation. Transfer of the fibre preparation from high $[Ca^{2+}]$ solution (pCa = 3.6) to an identical solution containing 5 µM calmodulin resulted in a further increase in tension.

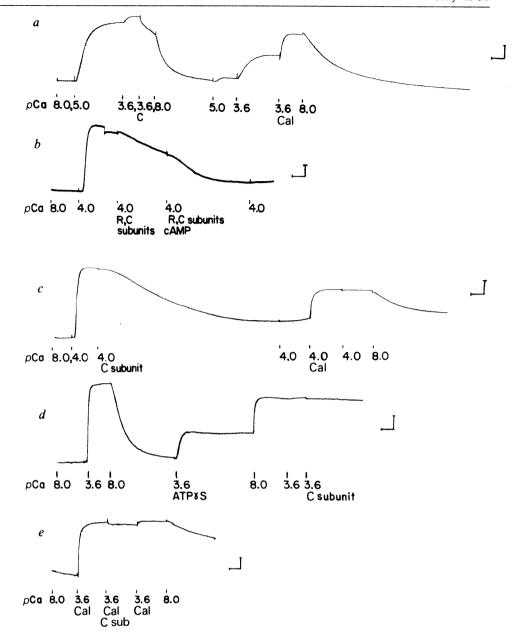

Figure 1b shows that after a maximal Ca2+-activated contraction, addition of both the regulatory and catalytic subunits of protein kinase results in a slow inactivation of the fibres and that addition of cyclic AMP (10⁻⁴ M) produces faster relaxation. Cyclic AMP is known to activate protein kinase by dissociation of the catalytic subunit from the regulatory subunit⁴; the free catalytic subunit is then able to inhibit the fibres. Initial slow inactivation of the fibre bundle is presumably due to either the production by the fibres of small amounts of cyclic AMP from ATP, or incomplete association of mixed catalytic and regulatory subunits, or both. A higher than physiological concentration of cyclic AMP was used to avoid diffusional problems associated with cyclic AMP binding sites in the fibres. After maximal activation of the fibre bundle (pCa = 4.0, Fig. 1c) and inhibition by the catalytic subunit, immersion of the fibres in a solution containing high [Ca2+] but no catalytic subunit resulted in little detectable activation of the fibres over the time period observed. However, in the presence of high [Ca²⁺] plus calmodulin, the fibres contracted immediately, giving partial recovery

Figure 1d shows that after a skinned fibre bundle had been pretreated with high [Ca²⁺] and adenosine 5'-O-(3-thiotriphosphate) (ATPyS) to irreversibly thiophosphorylate the myosin LC₂₀ light chains, the fibre bundle became fully activated when immersed in a solution containing ATP and no calcium (pCa = 8.0) and showed no further increase in tension in high $[Ca^{2+}]$ solution (pCa = 3.6). Following this irreversible thiophosphorylation and tension activation, addition of the catalytic subunit was unable to inactivate the fibre bundle. Thus when the light chains are irreversibly thiophosphorylated 10-13, the catalytic subunit of protein kinase can no longer inhibit the contraction. In the presence of 5 µM calmodulin (Fig. 1e), 1 µM catalytic subunit produced very little change in Ca²⁺-activated tension generation, in contrast to its action in the absence of calmodulin. The results shown in Fig. 1 are typical of results obtained with either the skeletal or cardiac catalytic subunit of cyclic AMP-dependent protein kinase.

Our data thus agree with the light chain kinase/phosphatase mechanism for Ca²⁺ activation of smooth muscle and the proposed inhibition of this mechanism by the catalytic subunit of the cyclic AMP-dependent protein kinase 16-18. The model proposed by Adelstein et al. 16.17, in which the phosphorylation of the high molecular weight subunit of light chain kinase by the catalytic subunit of the cyclic AMP-dependent protein kinase decreases the ability of the Ca²⁺-binding subunit of calmodulin to interact with it, predicts that tension would be inhibited by this catalytic subunit and the inhibited fibres would appear less sensitive to calcium (Fig. 1a). Once the fibres have been inhibited partially (Fig. 1a) or completely (Fig. 1c), addition of calmodulin should increase the Ca2+ sensitivity of the muscle according to the law of mass action. Also, once the LC₂₀ light chains have been irreversibly thiophosphorylated by the use of the ATP analogue ATP_YS¹⁰⁻¹³, inhibition of the light chain kinase by the catalytic subunit should have no effect on tension development (Fig. 1d). As the only site of irreversible thiophosphorylation is myosin LC₂₀ (ref. 11), the site of action of cyclic AMP-dependent protein kinase cannot be the thin

Fig. 1 Tension-time records of chicken gizzard skinned fibres. All solutions contained ATP unless indicated by ATPyS. Additions to the solutions are indicated below the pCa value and refer only to that solution, not to subsequent ones. a, Effect of 1 µM cardiac catalytic (C) subunit of cyclic AMP-dependent protein kinase on submaximal Ca2+ activated tension. Recovery of maximum tension with $5\,\mu M$ calmodulin (Cal) is shown. Vertical calibration bar, 8.3 mg. b, Inhibition of Ca2+-activated tension by 1 μM catalytic (C) subunit plus 2 μM cyclic AMP-free regulatory (R) subunit of skeletal cyclic AMP-dependent protein kinase, followed by addition of cyclic AMP (cAMP, 10^{-4} M). Vertical calibration bar, 1.9 mg. The mechanical artefact seen during the initial pCa = 4.0 concentration was due to a small knock to the table. c. Complete inhibition of Ca2+ activated tension by 1 µM skeletal catalytic (C) subunit of cyclic AMP-dependent protein kinase followed by partial recovery with 5 μM calmodulin (Cal). Vertical calibration bar, $11.1\,\text{mg}$. d, Lack of tension response to $1\,\mu\text{M}$ catalytic (C) subunit of cardiac cyclic AMP-dependent protein kinase after pretreatment (irrethiophosphorylation of 20,000-MW myosin light chains) of the fibre bundle with high $[Ca^{2+}]$ (pCa = 3.6) and ATPyS. Vertical calibration bar, 10.0 mg. e, Lack of inhibition by 1 µM cardiac catalytic subunit (C sub) in the presence of 5 uM calmodulin (Cal). Vertical calibration bar, 6.1 mg. The horizontal calibration bar represents 5 min in each case. Sections of muscle (~1-2 mm³) were cut from fresh chicken gizzards and lightly homogenized by a method described elsewhere for striated muscle²⁰ and previously used in this laboratory for gizzard skinned fibre pre-parations¹¹. Small bundles of fibres were visualized by background light using a binocular microscope and the two ends of a fibre bundle were clamped in small stainless steel forceps of a tension transducer apparatus similar to that of Hellam and Podolsky²¹. The fibres were activated and relaxed by transferring them to different test bathing solutions containing various amounts of Ca2+ and protein concentrations. The solutions contained 70 mM K⁺ + Na⁺, 1 mM Mg²⁺, 2 mM Mg-ATP2-, 15 mM creatine phosphate, 15

units of creatine phosphokinase (CPK) per ml solution, 82-84 mM imidazole, 7 mM EGTA total, varying amounts of Ca^{2+} (pCa = 8-3.6) and propionate as the major anion. The pH was kept constant at 7.00 (± 0.02) and the ionic strength kept at 0.15 by varying the amount of imidazole propionate. However, the solution in which ATP γ S was substituted for ATP contained 85 mM K⁺ + Na⁺ and no creatine phosphate/CPK regenerating system, but was otherwise identical to the solutions described above. The total concentrations of magnesium, potassium and calcium propionate, disodium ATP, disodium creatine phosphate and imidazole required were determined by a computer program using binding constants obtained from the literature²².

filament, proposed by Nonomura and Ebashi¹⁹ to regulate smooth muscle by a leiotonin system. Furthermore, the presence of calmodulin prevents the inhibition of tension by the catalytic subunit (Fig. 1e). If phosphorylation of the 125,000-molecular weight (MW) light chain kinase decreases its interaction with calmodulin¹⁷, the presence of added calmodulin should overcome this by the laws of mass action. We will present elsewhere a detailed study of the relationship between increased phosphorylation of myosin light chain kinase, decreased phosphorylation of LC₂₀ light chain and inhibition of tension generation.

We have treated two other smooth muscle types, skinned using Triton X-100, with the catalytic subunit of protein kinase and obtained the same results as for chicken gizzard. These muscles were rabbit pulmonary artery and the aorta from the Pacific Coast dogfish which evolved 400 Myr ago. Therefore, the mechanism for this inhibition of tension in smooth muscle by cyclic AMP-dependent protein kinase seems to have evolved before much of the animal kingdom as we know it today.

These data show for the first time that the catalytic subunit of protein kinase can inhibit the physiological variable, Ca²⁺-

activated tension, in skinned smooth muscle fibre preparations. Pretreatment of the smooth muscle fibres with this catalytic subunit causes a decrease in the apparent Ca^{2+} sensitivity of the muscles, an effect which can be reversed by the addition of calmodulin. In the presence of both the catalytic and regulatory subunits of protein kinase, addition of cyclic AMP increased the rate of inhibition of tension. These results agree with the mechanism described elsewhere ^{16,17}, which involves this protein kinase system in the β -adrenergic relaxation of smooth muscle, but do not support the thin filament control mechanism proposed by Nonomura and Ebashi¹⁹.

We thank L. Bolles and R. Coby for technical assistance, Dr J. Beavo for gifts of cyclic AMP-free regulatory subunit of the peak-1 bovine skeletal muscle cyclic AMP-dependent protein kinase and bovine skeletal catalytic subunit; Drs E. H. Fischer and E. Krebs for bovine cardiac catalytic subunit of cyclic AMP-dependent protein kinase, and Drs E. H. Fischer and D. Malencik for gifts of bovine brain calmodulin. This research was supported by grants from the Muscular Dystrophy Association, American Heart Association and NIH. P.E.H. was supported by a fellowship from the Muscular Dystrophy Asso-

ciation. The chicken gizzard muscles were supplied by Acme Poultry Co.

Recent experimental evidence indicates that progesterone acts at the cell surface to trigger protein synthesis and to reinitiate the first meiotic division in Xenopus laevis oocytes1,2. The steroid hormone is physiologically released by follicle cells surrounding oocytes in the ovaries, and this naturally occurring event can be reproduced in vitro by adding progesterone to the incubation medium. Recently, cyclic AMP has been implicated in the mechanism of progesterone action in oocytes3,4; there was an almost immediate decrease in cyclic AMP concentration in oocytes after addition of progesterone in vitro, whether or not the oocytes were pretreated with cholera toxin5,6. Adenylate cyclase in X. laevis oocytes is compartmentalized, >50% soluble and ~30% is found in the plasma membrane-containing fraction⁷. We report here that physiological concentrations of progesterone selectively inhibit membrane-bound adenylate cyclase activity, after addition to intact oocytes or in cell-free experiments; this specificity confirms the proposed membrane site of action for the hormone when reinitiating meiosis and is the first example of a 'direct' enzymatic action of a steroid (not by protein synthesis) related to a physiological function.

Adenylate cyclase activity in oocytes was measured in four subcellular fractions isolated by differential centrifugation (Fig. 1a), and was largely found in two compartments, a 10,000g pellet (P-10,000; 20-30%) and the cytosol (50-65%), a distribution similar to that observed in the early stages of male germ-cell development⁸. Both particulate and soluble forms of the enzyme appeared equally active in the presence of either Mg²⁺ or Mn²⁺, but only the particulate activity was stimulated (two- to threefold) by 10 mM sodium fluoride. Electron microscopic examination of P-10,000 showed a uniform vesiculated membrane structure and enzyme patterns suggested an enrichment in plasma membrane. Incubation of oocytes with progesterone produced a rapid inhibition of the P-10,000associated cyclase. Its specific activity was reduced by 65% while the soluble activity was unchanged. Cycloheximide had no effect on particulate cyclase inhibition. The facts that only the membrane-bound cyclase was inhibited by progesterone, and that more than half of the oocyte enzymatic activity is soluble, explain the limited decrease in total cyclic AMP observed in intact oocytes. Therefore, cholera toxin was used to magnify the progesterone-induced decrease of cyclic AMP in oocytes; after cholera toxin has been added to increase cyclic AMP levels (to 150-300% of control), the addition of progesterone produces an immediate decrease to basal level⁶. Adenylate cyclase determinations confirmed the dual nature of the enzyme in oocytes, as only the P-10,000 cyclase was stimulated by cholera toxin (5-10-fold), while this stimulation was reversed by addition of progesterone to the oocyte incubation medium just before cell fractionation (Fig. 1b).

To demonstrate that progesterone interacts directly with the plasma membrane cyclase activity, without an intermediary

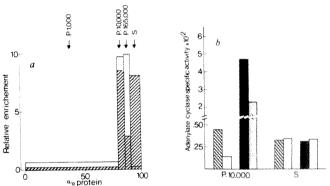

Fig. 1 Adenylate cyclase activity in subcellular fractions of untreated and progesterone- and/or cholera toxin-treated X. laevis oocytes. Fully grown oocytes, obtained as described elsewhere4, were washed and homogenized in 10 vol of 1 mM NaHCO3, 3 mM EDTA, at 4 °C, with a Dounce apparatus (pestle A, 10 strokes). The homogenate was centrifuged at 1,000g for 15 min; the pellet (P-1,000) contained most of the vitellus and melanosomes. The supernatant was centrifuged at 10,000g for 20 min and the P-10,000 pellet separated. The supernatant was again centrifuged at 165,000g for 15 min, and both the supernatant (S) and the pellet (P-165,000) were retained. All pellets were resuspended in the same buffer and enzymatic assays were performed immediately. Adenylate cyclase assays were done in 60 μ l containing 1 mM [α - 32 P]ATP (10^6 c.p.m.), 3 mM MgCl₂, 1 mM EDTA, 1 mM cyclic AMP, 50 mM Tris-HCl pH 7.6, plus an ATPregenerating system consisting of 25 mM phosphocreatine and 1 mg ml creatinine phosphokinase. The reaction was terminated by a modification ¹⁴ of the procedure of White ¹⁵. In these conditions, the degradation of ATP was negligible and the enzymatic activity was linear with time up to 60 min and linear with protein up to 60 µg per assay; this was also the case for inhibition experiments. Labelled cyclic AMP was isolated according to Rachamadran 16. The yield was calculated by previous addition of cyclic [8-3H]AMP; it was unchanged when the experiment was performed in the presence of steroids, eliminating a significant stimulation of the phosphodiesterase(s) by the steroids. 5'-nucleotidase activity was estimated as described elsewhere¹⁷. The distribution pattern of adenylate cyclase (22) in oocytes is shown in a, superimposed on that of 5'-nucleotidase (

). Enzyme activities and protein concentrations were measured in the whole homogenate and in the separated fractions. Relative enrichment for adenylate cyclase is the ratio of specific activity in each fraction divided by specific activity of the whole homogenate. This parameter is plotted against the percentage of the whole homogenate protein recovered in each fraction. The area of the bars is proportional to the recovery of the enzyme in the corresponding fractions. The ordinate measures the degree of purification achieved over the whole homogenate value. The same representation is used for 5'-nucleotidase. b, Adenylate cyclase specific activities in P-10,000 and S fractions of untreated occytes (cross-hatched bars), occytes preincubated with 30 µM progesterone for 90 s (open bars), oocytes preincubated with 50 pmol cholera toxin for 6 h (solid bars), and oocytes incubated with 30 µM progesterone for 90 s at the end of the preincubation with cholera toxin (stippled bars). Cyclase activity is expressed as pmol of cyclic AMP formed in 15 min per mg protein at 32 °C. Protein and 5'-nucleotidase values were identical in control and progesterone/cholera toxin-treated oocytes (data not shown).

state involving a metabolic change, we performed cell-free experiments. We found that P-10,000 adenylate cyclase from control oocytes was inhibited by addition of progesterone in the enzymatic assay at 20 °C—the physiological temperature for the maturation process—as well as at 32 °C, the optimal temperature for the cyclase assay. There was no lag phase and the decrease in cyclase activity persisted for at least 60 min (in agreement with the prolonged reduction in cyclic AMP level observed in intact oocytes⁶). Progesterone-induced inhibition of cyclase activity was dose dependent: $K_i \sim 0.1 \,\mu\text{M}$ (that is about one order of magnitude lower than the half-maximal effective dose of progesterone when initiating meiosis, as if some trapping or inactivation of the hormone in intact oocytes may be eliminated in the cell-free system). In most cases, maximum inhibition (at 10 µM) reached 80% of control activity. Progesterone reduced the $V_{\rm max}$ of the enzyme without changing the apparent affinities for MgATP and MnATP substrates, and for the activators free Mg²⁺ and free Mn²⁺ (data not shown). Finally, cyclase activity was entirely recovered after extensive membrane washing, which demonstrates the reversibility of progesterone inhibition. Adenylate cyclase activities stimulated by NaF or guanyl-5'-yl imidodiphosphate (Gpp(NH)p, a GTP analogue not hydrolysed to GDP by GTPases in membranes) were also inhibited by progesterone, which also reversed enzyme stimulation in P-10,000 obtained from oocytes preincubated with cholera toxin (Fig. 2). In all these assay conditions, inhibition by progesterone was dose dependent with an apparent K_i similar to that found in basal conditions. This effect of progesterone seemed to be different from the GTP-dependent inhibitions so far described, which are prevented by stable GTP analogues and generally abolished by cholera toxin pretreatment9. Progesterone inhibition did not seem to be mediated by an adenosine effect as it was not suppressed by adenosine desaminase in the assay; adenosine and progesterone inhibitions of cyclase in oocyte membranes were additive⁷

Furthermore, progesterone-induced inhibition of adenylate cyclase does not seem dependent on Ca^{2+} concentrations. In intact oocytes, progesterone effect was observed in Barth's medium containing 1 mM CaCl₂, while in cell-free experiments steroid inhibition occurred in the presence of 1 mM EDTA. In vitro, Ca^{2+} -induced inhibition of cyclase $(K_i = 0.5 \text{ mM})$ and progesterone inhibition were additive, which suggests that these

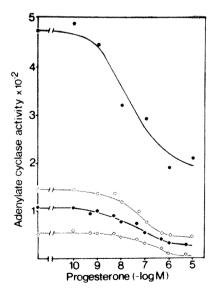

Fig. 2 Inhibition by progesterone of membrane adenylate cyclase activity in X. laevis oocytes treated with cholera toxin or untreated. The P-10,000 fraction was obtained from untreated X. laevis oocytes $(\diamondsuit, \blacklozenge, \bigcirc)$ or from oocytes preincubated for 6 h with 50 pM cholera toxin (\clubsuit) . Progesterone was added in the enzymatic assay, with no other addition $(\diamondsuit, \spadesuit)$, or with 10 mM sodium fluoride (\diamondsuit) or $1 \mu M$ Gpp(NH)p (\bigcirc) . The reaction was initiated by addition of P-10,000 (50 μg protein per assay) to the enzymatic assay medium. Adenylate cyclase activity is expressed as pmol of cyclic AMP formed in 15 min per mg protein.

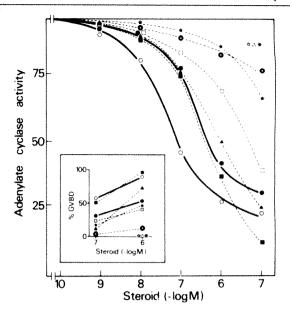

Fig. 3 Membrane adenylate cyclase of X. laevis oocytes: specificity of steroid inhibition. The P-10,000 fraction was incubated with 1 μM Gpp (NH)p and steroids. Adenylate cyclase activity at each concentration of steroid tested is expressed as per cent of the activity measured in the absence of hormone. Percentage of germinal vesicle breakdown (GVBD) is indicated in the inset. It was routinely determined on 30-50 oocytes after 8 h incubation by scoring the appearance of the 'white spot' at the animal pole. Experiments were done exactly as described elsewhere 4. The steroids tested were: progesterone (①); progesterone +10 μM 17α-ethynyloestradiol (①); testosterone (③); cortisone (▲); dehydroepiandrosterone (□); hydrocortisone (★): 19-nortestosterone (Φ); oestrone (★).

two inhibitors use different mechanisms. However, we cannot exclude the possibiltiy that changes in Ca²⁺ contribute to the inhibition of adenylate cyclase activity in intact oocytes.

The inhibitory steroid effect showed the same hormonal specificity as that reported for maturation in intact oocytes. In the P-10,000 cell-free system, testosterone and cortisone, which are almost as efficient in promoting meiosis as progesterone, were also the most active inhibitors of adenylate cyclase ($K_i = 0.1 \,\mu\text{M}$). Dehydroepiandrosterone, cortisol and 19-nortestosterone only reached 2/3-1/3 of the progesterone inhibitory activity, with an apparent $K_i \sim 1 \,\mu\text{M}$; oestrone, 17 α -ethynyloestradiol and progestrone (1,3,5-pregnatrien-3-ol, 20-one) were not active. Moreover, we found that 17 α -ethynyloestradiol, which antagonizes progesterone-induced meiosis apparently in a competitive manner 10, displaced to the right by one order of magnitude the dose-dependent curve of cyclase inhibition by progesterone (Fig. 3).

These results provide the first example of a direct enzymatic action of steroids in a physiological mechanism, the enzyme being a typical plasma membrane component. Intriguing studies with glutamate deshydrogenase demonstrated that steroids can have allosteric effects on the enzyme¹¹, and it has been suggested that this could be an important mechanism for hormone action¹². However, the lack of hormonal specificity made this model system irrelevant to a physiological system. The remarkable correlation between steroid action on meiosis and on membrane adenylate cyclase inhibition strongly suggests that we are dealing with a biochemical event relevant to the biological phenomenon. Experiments are now being done to determine whether other steroid systems show characteristics similar to those observed in oocytes¹³.

Differences between oestrogen receptor activation by oestrogen and antioestrogen

Henri Rochefort & Jean-Louis Borgna

Unité d'Endocrinologie Cellulaire et Moléculaire, U 148 INSERM, 60, rue de Navacelles, 34100 Montpellier, France

Triphenylethylene antioestrogens such as tamoxifen, nafoxidine and Ci 628 specifically inhibit oestrogen action at the target cell level¹, probably by interacting with the oestrogen receptor (ER) and competitively displacing oestrogens from their binding sites. It is not clear, however, why these ligands are less biologically active than oestrogens when they bind to the ER, as no reliable difference has been found either in the binding affinity of these two series of ligands to the ER or in their ability to translocate the ER to the nucleus1,2. In fact, these antioestrogens are transformed in vivo into hydroxylated metabolites3-5 which display a better antioestrogenic activity than the injected compound and at least the same high affinity as oestradiol for the ER6. With the aim of finding an in vitro criterion to predict the agonistic or antagonistic properties of ER ligands, we have stabilized the ER in its 'native' or non-activated form by the use of molybdate7,8 and have compared the binding of oestradiol (E2) and of 4-hydroxytamoxifen (OHT), an active metabolite of tamoxifen, to the molybdate-treated and to the activated ER. We report here that molybdate prevented the DNA binding and the 4S to 5S transformation of the ER bound to both ligands, and that it increased the dissociation rate of oestrogens but not that of antioestrogens. Moreover, in the absence of molybdate, receptor activation by heating decreased the dissociation rate of E2 but not that of OHT. We conclude that a difference exists between the ER activation triggered by oestrogens and antioestrogens and propose that antioestrogens are acting as allosteric ligands of the ER.

We have looked at three series of in vitro criteria for receptor activation. The first classical criterion is the increased affinity of the receptor for DNA and nuclei. The ability of lamb uterine ER to interact in vitro with calf thymus DNA was evaluated by ultracentrifugation in sucrose⁶ and metrizamide⁹ gradients. In the absence of molybdate, both the ER-E2 and the ER-OHT complexes bound to DNA, confirming that OHT also activate the ER for binding to DNA in vitro⁶ and for translocating the ER into the nucleus1. With molybdate, the DNA binding of the ER was totally inhibited whether ER was bound to an antioestrogen (OHT) or to an oestrogen (E2). A second in vitro test for ER activation is the E2-induced 4S to 5S transformation 10 which is also prevented by molybdate. However, both OHT and E₂ were able to transform the cytosol 4S ER into a 5S ER in the immature rat uterus and both processes were prevented by molybdate.

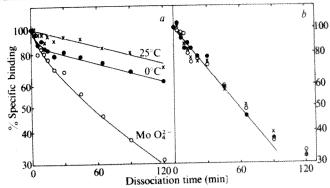

Fig. 1 Dissociation rate of oestradiol (a) and 4-hydroxytamoxifen (b) from the oestrogen receptor before and after heat activation. Lamb uterine cytosol (2 mg protein per ml) prepared in TE buffer (Tris-HCl 10 mM, EDTA 1.5 mM, pH 7.4) in the presence (O) or absence (\bullet , ×) of 10 mM MoO₄² was incubated for 2 h with 5 nM ³H-oestradiol (E_2) (CEA: Specific activity 55 Ci mmol⁻¹) or ³H-4-hydroxy-trans-tamoxifen (OHT) (specific activity 15.8 Ci mmol⁻¹) prepared biologically from ³Htamoxifen or provided by ICI. One part of the cytosol without MoO₄²⁻ was activated by a 30-min treatment at 25 °C, the other part was maintained at 0 °C, the dissociation rate was then determined at 25 °C as described elsewhere⁶, following the addition of $1 \mu M$ unlabelled E_2 at time 0. At the indicated times, aliquots were removed and cooled at 0 °C. The specific binding to the ER was determined after 90 min incubation with charcoal suspension⁵; the non-specific binding was evaluated in a parallel experiment performed with 1 µM unlabelled E2. Results were normalized by taking the pre-dissociation value as 100%. The complexes were stable during the course of the assay. × (25 °C), preactivated ER; (0 °C), non-preactivated ER; ○ (MoO₄²), mollybdate-treated ER.

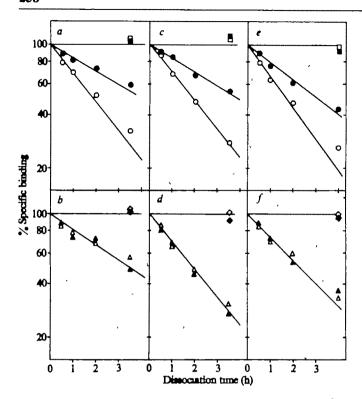

Table 1 Effect of molybdate on the dissociation rate (k^{-}) of various oestrogens and antioestrogens from the oestrogen receptor

a, Species specificity ($(k^-, \times 10^-)$	-4 s ⁻¹)				
	Calf	Lamb	Rat	Mouse	Chicken	MCF ₇
Temperature (°C)	20	20	20	20	15	20
E_2						
Control	0.47	0.14	0.64	1.27	0.68	0.51
+Molybdate	1.10	0.28	2.40	4.01	1.75	1.04
% Increase	135	100	275	215	155	105
OHT						
Control +Molybdate	0.56	0.47	0.69	0.88	0.20	1.92
% Increase	0 ± 10	~0	~0	~0	~0	~0

b, Ligand specificity $(k^-, \times 10^{-4} \text{ s}^{-1})$

	Temperature (°C)	Control	+Molybdate	% Increase
E ₂	20	0.14	0.28	100
E ₁	20	6.60	11.91	80
E ₃	20	0.31	0.58	120
5-Adiol	0	0.63	1.13	80
OHT	20	0.47	0.47	∞=()
T	0	2.30	2.30	= 0
Ci 628	0	0.85	0.85	≈0

a, Species specificity: the dissociation rate constants of E2 and OHT from the cytosol ER of calf, lamb, rat and mouse uterus, of chicken oviduct and of the MCF7 human breast cancer cell line were determined at 20 °C or 15 °C (chicken), following heat 'activation' in the presence or absence of 10 mM sodium molybdate as described in Fig. 2 legend. The values calculated after correction for nonspecific binding and their percentage increase due to molybdate are presented. For OHT studies, the difference between the two linear regressions drawn through the points obtained with and without molybdate was zero or less than 10%. We have therefore represented only the mean values. b, Ligand specificity: the k from the cytosol ER of lamb uterus has been determined at 20 or 0 °C as described in Fig. 2 legend for various oestrogens (oestradiol = E_2 ; oestrone = E_1 ; oestriol = E_3 ; and osta-5-ene-3 β , 17 β diol = 5-Adiol) and antioestrogens (CI 628; tamoxifen = T; 4hydroxytamoxifen = OHT).

Recently, a third criterion has been proposed^{6,11,12}, the slower dissociation rate of oestrogens from the activated ER than from the 'native' non-activated ER. We therefore compared the dissociation rate at 25 °C for ³H-E₂ and ³H-OHT (Fig. 1). As already described², the dissociation rate from the cytosol ER varied according to whether the cytosol was treated at 0 °C or was preheated at 25 °C to activate the complex. In the initially non-activated ER, the dissociation of ³H-E₂ was biphasic. The first slope was more rapid than the second which corresponded to the activated complex formed during dissociation. When the cytosol ER had been preactivated, the dissociation was monophasic and parallel to the second slope. Conversely, with ³H-OHT, no difference of dissociation could be seen whether or not the cytosol was preheated at 25 °C. This suggested a difference of activation between the ER-E₂ and ER-OHT complexes. Because the measurement of the dissociation rate for these high-affinity ligands required elevated temperature which also activated the receptor, we then tried to stabilize the native non-activated receptor by using molybdate.

As seen in Fig. 1, the ER-E2 complex continued to dissociate at the initial rate in the presence of molybdate, which apparently prevents the activation process. Conversely, we found no difference for the dissociation of ³H-OHT from the ER. This seems to be a general phenomenon because, in all species tested, the dissociation of E2 was more rapid from the molybdatestabilized ER, whereas that of OHT was generally not modified by molybdate (Fig. 2, Table 1). In the rat and mouse uterus where antioestrogens are partial agonists 13, the dissociation rate of OHT was also unchanged by molybdate. However, in these species, the metabolite(s) responsible for the agonist activity are unknown. Other oestrogens—oestrone, oestriol and androsta-5-ene, 3B, 17B-diol (5-Adiol)—which bind to the ER with a K_D of 6 nM (ref. 14), also dissociated more rapidly from the ER stabilized with molybdate than from the untreated ER (Table 1b). Conversely, the dissociation rate of the other anticestrogens, tamoxifen and Ci 628, was not altered by molybdate in lamb uterus.

These kinetic experiments indicate an increased affinity of E_2 for the ER during its activation, in contrast to a relatively constant affinity of anticestrogens for the ER. Thus, when anticestrogens compete with E_2 for binding to the ER, the competition should be more effective initially and should diminish progressively with time, E_2 displacing the antices-

Fig. 2 Effect of molybdate on the dissociation rate of oestrogens and anticestrogens from the cestrogen receptor. a, b, Calf uterine cytosol prepared with (\bigcirc, \triangle) or without (\bigcirc, \triangle) 10 mM MoO₄ was incubated for 2 h with 5 nM 3 H-E₂ (\bigcirc, \bigcirc) or 3 H-OHT (\triangle, \triangle) . The cytosol ER was then heated for 30 min at 25 °C and the dissociation rate at 20 °C was evaluated as described previously⁶. Each value was corrected for nonspecific binding. The stability of the complexes was assayed separately $(\Box, \mathbf{m}, \diamondsuit, \spadesuit)$. Results were normalized by taking the pre-dissociation value as 100%. c, d, Same experiment with cytosol of the MCF7 human breast cancer cells. The ER was activated at 20 °C. e, f, Dissociation rate at 0 °C from lamb uterine cytosol incubated with 20 mM ³H-androsta-5ene, 3β,17β-diol (O, ●) (specific activity 58.6 Ci mmol⁻¹) or Cl 628 (Δ, \blacktriangle) (22.5 Cl mmol⁻¹), both from the Radiochemical Centre), in the presence or absence of 2 µM diethylstilboestrol to assay nonspecific binding. After heating for 30 min at 25 °C, the dissociation of the ligands at 0 °C was assayed by adsorption with charcoal for 30 min at 0 °C.

trogen from the ER. We have previously observed such a displacement 15. To specify whether this displacement was due to the activation of the ER or simply to a lack of equilibrium between the two ligands and the ER 16, we have tested the effect of molybdate during competition of 3H-E₂ binding by tamoxifen. Figure 3 shows that the competitive efficiency of tamoxifen was increased by the addition of molybdate. However, the time-dependent increase of E₂ binding was still observed, suggesting that it was due partly to a lack of equilibrium and partly to receptor activation.

The action of non-steroidal antioestrogens is mediated either by the ER as classically proposed or by other receptor entities, such as the recently described¹⁷ protein binding specifically anti-oestrogens. In support of the latter hypothesis, we have found in MCF7 breast cancer cells, which do not metabolize tamoxifen or OHT, that OHT is more active than tamoxifen in inhibiting the induction by E₂ of a 46,000 molecular weight protein¹⁶ and in preventing cell growth¹⁹. However, the finding that the effect of antioestrogens in MCF7 cells 20 and in chick liver is fully and rapidly reversed by the addition of oestrogens. strongly suggests that these antioestrogens are simply acting by competing with oestrogens on the ER. Nevertheless, it is not clear why the ER-antioestrogen complex is not fully active or is in some cases totally unable to induce oestrogen-specific proteins. The simplest explanation is that the E₂-induced activation of the ER is different from that triggered by an antioestrogen. This altered activation of the ER by antioestrogen might therefore be detectable before the nuclear translocation step, even though its consequence will be located at sites of interaction with chromatin. An alternative hypothesis is an altered interaction with chromatin of a normally activated ER-antiquestrogen

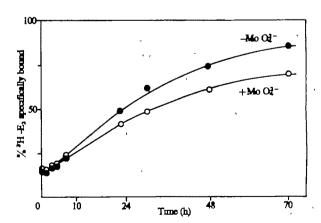

Fig. 3 Time-dependent variation of competitive efficiency of tamoxifen and effect of molybdate. Lamb uterine cytosol was incubated in the presence (○) or absence (●) of molybdate with 2 nM ³H-E₂±0.5 μM tamoxifen for the indicated time periods. The ³H-E₂-specific binding was determined by charcoal assay ⁶ and the binding obtained in the presence of tamoxifen was expressed as a percentage of the non-inhibited binding at each point.

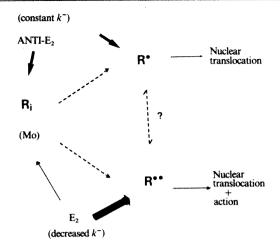

Fig. 4 A model for two types of oestrogen receptor activation induced by oestrogens or antioestrogens. The native ER (Ri) is in the cytosol. After interaction with antioestrogens (anti-E2), it is activated for nuclear translocation (R*) but not for a complete action. After interaction with oestrogens (E2), the ER is fully activated for nuclear translocation and for action (R**). We propose to differentiate between the two types of activation by measuring the in vitro dissociation rate of ligands from the molybdate-stabilized Ri and the activated R. Whereas oestrogens dissociate at a slower rate from R** than from R_i, antioestrogens dissociate at the same rate from both R* and R_i. The width of the full arrows indicates the relative affinity of the ligands for each receptor state.

complex. This could be envisaged, for instance, as a direct interaction of the free drug with DNA or protein in chromatin. Our results strongly support the first possibility. This difference of activation by antioestrogens is detected before the translocation step by simply analysing the dissociation rate of the antioestrogen from the ER with and without molybdate. The consequence of this impeded activation is probably located at the chromatin level, where the ER is thought to trigger the first biochemical responses.

As the oestrogens but not the antioestrogens are able to transform the ER-ligand complex into a more slowly dissociating form, although both ligands can induce the ER nuclear translocation, we propose two kinds of ER activation (Fig. 4). The first (R*) would be obtained after binding of any ligand, oestrogen or antioestrogen, and would trigger a covalent or conformational change of ER allowing its nuclear localization. The second type of activation (R") would be obtained only after binding to oestrogens and would induce a more complete modification of the ER, giving a full metabolic response. A practical in vitro criterion for a full biological activation of the receptor would therefore be a modification of the ER binding site such that the dissociation rate of agonists, but not antagonists, is reduced. It is thus possible to discriminate between oestrogen agonists and antagonists by simply comparing the dissociation rate constants of the ligands from the molybdate-stabilized (non-activated) and from the activated forms of the ER. Note that it is not the actual value of the k^- , but rather its variation during ER activation, which characterizes an active oestrogen. In this model, the affinity of the antioestrogen for the activated and non-activated ER would be similar, whereas the affinity of oestrogen would be higher for the activated form of the ER. We propose that antioestrogens act as allosteric²² ligands which stabilize the ER in inactive (R_i) or partially activated form (R*), whereas oestrogens stabilize the receptor in a fully activated form (R**). These results further support the generally accepted idea that antioestrogens act via the ER and not via a distinct receptor molecule specific for antioestrogens.

We thank Dr Todd (ICI) for providing ³H-tamoxifen and ³H-4-hydroxytamoxifen, Dr D. Bullock for critical reviewing of the manuscript, S. Ladrech for technical assistance and E. Barrié

Human transforming growth factors induce tyrosine phosphorylation of EGF receptors

Fred H. Reynolds Jr*, George J. Todaro†, Charlotte Fryling† & John R. Stephenson†

† Laboratory of Viral Carcinogenesis, National Cancer Institute, Frederick, Maryland 21701, USA

Cultured cell lines of human tumour origin as well as cells transformed by various RNA tumour viruses secrete low molecular weight polypeptide transforming growth factors (TGFs)1.2. In addition to competing with epidermal growth factor (EGF) for binding to its cellular receptor, TGFs can transform morphologically fibroblast and epithelial cells in culture 1-3. In view of accumulating evidence that tyrosine phosphorylation activity is associated with the transforming genes of various tumour viruses⁴⁻¹³, we determined whether phosphotyrosine levels were elevated in these human tumour cells. We show here that TGFs produced by human tumour cells induce phosphorylation of specific tyrosine acceptor sites in the 160,000molecular weight (160 K) EGF receptor.

The demonstration of increased levels of phosphotyrosinecontaining proteins in cells transformed by avian³⁻⁸ and mam-malian⁹⁻¹³ RNA tumour viruses raises the question of whether RNA tumour viruses raises the question of whether regulatory pathways which involve tyrosine phosphorylation may also have significance in the aetiology of spontaneous and chemically induced tumours. We therefore examined phosphotyrosine levels in several established human tumour cell lines. Of six independently derived lines analysed, none showed overall phosphotyrosine concentrations that were significantly greater than those of untransformed control Fisher rat embryo cells (Table 1). Similarly, we (data not shown) and Sefton et al.⁵ have analysed many non-virally transformed mammalian cells of other than human origin and found that the phosphotyrosinecontaining protein levels are comparable with those of untransformed cells. In analogous assay conditions, as reported elsewhere 5.9.12.13, cells transformed by either Gardner feline sarcoma virus (FeSV) or Abelson murine leukaemia virus (AbLV) show 8-10-fold increases in phosphotyrosine levels,

Table 1 Phosphotyrosine levels in human tumour and Fisher rat cells after exposure to either EGF or human TGF

	Phosphotyrosine	(% of total acids) EGF-	phosphoamino TGF-
Cell line	Untreated	stimulated	stimulated
Human tumour:			
A431 carcinoma	< 0.2	2.6	2.4
A673 rhabdomyosarcoma	< 0.2	< 0.2	< 0.2
A2058 melanoma	0.4	0.4	< 0.2
A875 melanoma	< 0.2	0.3	NT
JARC2 carcinoma	< 0.2	< 0.2	NT
A204 rhabdomyosarcoma	< 0.2	< 0.2	NT
Fisher rat:			
Control	< 0.2	< 0.2	< 0.2
AbLV-transformed	1.9	2.0	NT
G-FeSV-transformed	1.7	1.9	1.8
M-MSV-transformed	< 0.2	< 0.2	NT

Cell lines were cultured in Dulbecco's modification of Eagle's medium as described previously¹. Phosphotyrosine determinations were performed by incubation of cells in medium containing ^{32}P -orthophosphate $(1.0~\text{mCi ml}^{-1})$ and as indicated above, either EGF $(0.1~\text{µg ml}^{-1})$ or transforming growth factor (TGF $10~\text{µg ml}^{-1})$, partially purified from medium of A673 cultures. ^{32}P -labelled proteins were prepared, hydrolysed and phosphoamino acids subjected to two-dimensional separation on cellulose TLC plates as previously described¹³. Individual ^{32}P -labelled phosphoamino acids, including phosphoserine, phosphothreonine and phosphotyrosine, were scraped off TLC plates and radioactivity quantified by liquid scintillation counting. Results are expressed as ^{32}P label in phosphotyrosine as a percentage of label in total phosphoamino acids. NT, not tested.

while the levels of phosphotyrosine in Moloney sarcoma virus (MSV)-transformed cells are similar to those in control cell lines.

In view of the phenotypic response of embryo fibroblasts to TGFs and EGF-stimulated tyrosine-specific protein kinase activity associated with the EGF membrane receptors14 examined phosphotyrosine levels in human TGF- and mouse EGF-treated cells. As shown in Table 1, the human tumour line with the greatest concentration of available EGF receptors, A431 (refs 15, 16), showed a pronounced increase in total phosphotyrosine in response to either EGF or TGF, isolated from the culture fluids of the A673 rhabdomyosarcoma cell line¹. The overall extents of tyrosine phosphorylation in these growth factor-treated cells were comparable with those found in RNA tumour virus-transformed cells. Concentrations of phosphotyrosine in other cell lines, including A673 and A2058, which themselves are high-level producers of TGFs¹, remained unaltered after exposure to either human TGF or mouse EGF. Finally, the already elevated levels of phosphotyrosine in Gardner FeSV- and AbLV-transformed rat cells showed no further increase in response to either growth factor.

The A431 cell substrate(s) phosphorylated in response to TGFs were identified by an in vitro extract labelling procedure, which has been previously shown to result in preferential phosphorylation of tyrosine acceptor sites¹⁷. Figure 1 shows that phosphorylation of a 160,000-M_r major protein was observed after exposure of A431 cells to EGF for 1 min (lane a), but was not seen in control cells (lane c). ³²P-labelling of this substrate, designated P160, was observed at EGF concentrations as low as $0.01 \,\mu \text{g ml}^{-1}$ (Fig. 1, lane k), and was maximal at $1.0 \,\mu \text{g ml}^{-1}$ (Fig. 1, lane m). On the basis of both M_r and immunoprecipitation by an antiserum which specifically blocks binding of labelled EGF to the previously described 160 K EGF membrane receptor, this phosphorylated cellular substrate was thought to be the EGF receptor itself. Exposure of A431 cells for 1 min to 100 µg ml⁻¹ of either A673 human tumour-derived TGF (lane e) or sarcoma growth factor (SGF) isolated from supernatant fluids of MSV-transformed cells² (lane g) resulted in P160 phosphorylation comparable with that observed for higher levels of EGF (1.0 µg ml⁻¹). The higher specific activity of EGF as measured by stimulation of P160 phosphorylation or inhibition of 125I-labelled EGF binding reflects the fact that it was fully purified whereas the TGF and SGF used here were only 1% pure. In experiments in which the length of exposure to EGF or TGF was increased to 10 min before extract preparation, the extent of 32 P-labelling of P160 was considerably reduced and a second 32 P-labelled substrate of $\sim 35,000\,M_{\rm r}$ was observed. Analysis of Fisher rat cells for growth factor-induced phosphorylation of P160 showed no change in response to either EGF or TGF (Fig. 1, lanes f,h). Several lower molecular weight (20,000–40,000) proteins were phosphorylated in extracts of TGF- and SGF-treated rat cells but their significance is unknown. Other growth stimulatory factors including phorbol ester derivatives and insulin, when tested for stimulation of EGF receptor phosphorylation, had no effect in these assay conditions. Moreover, pretreatment of cells with phorbol ester derivatives in conditions previously shown to modulate EGF binding 18 by converting available sites from high to low affinity 19,20 , did not affect phosphorylation of P160 in response to either EGF or TGF.

Both the human and MSV-transformed mouse cell-derived factors have been further purified by HPLC²¹. Individual column fractions were assayed for inhibition of EGF binding, transformation of cultured rat embryo fibroblasts and stimulation of EGF receptor phosphorylation. All three activities copurified in a region of a column representing <2.0% of the total input protein which argues strongly that EGF receptor-induced phosphorylation was due to the respective TGFs. In other studies, heating these factors in conditions (100 °C, 5 min) which inactivate protein kinases neither destroyed the ability of TGFs to bind to EGF receptors nor altered P160-induced phosphorylation. Thus, the EGF receptor phosphorylation requires a kinase associated with the receptor. Binding of EGF, SGF, or TGF to this receptor alters its properties to give phosphorylation of the receptor protein.

These findings identify a substrate, P160, which is labelled in the presence of $[\gamma^{-32}P]$ ATP in extracts of growth factor-treated but not untreated control cells. To test whether these extracts represented tyrosine acceptor sites, the 160 K EGF receptor, phosphorylated in response to EGF or to TGF, using *in vitro* extract labelling conditions, was eluted from SDS-polyacrylamide gel electrophoresis gels by trypsinization, and subjected to phosphoamino acid analysis. Figure 2 shows that

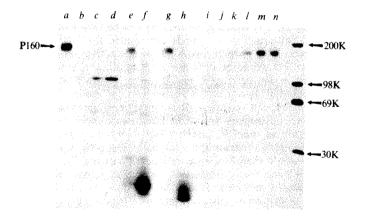

Fig. 1 SDS polyacrylamide gel electrophoresis (SDS-PAGE) analysis of substrates phosphorylated in A431 cell extracts in response to treatment with either mouse EGF or human TGF. A431 human tumour cells (a.c.e. g.in) and Fisher rat embryo cells (b,d,f,h) were grown to confluency in single wells (1 cm diameter) of 24-well cluster plates (Costar). Culture fluids were aspirated, and cells rinsed with 10 mM sodium phosphate pH 7.2, 100 mM NaCl and 5 mM MgCl₂. A total of 0.05 ml of the same buffer containing 0.001(j), 0.01(k), 0.1(l), 1.0(m) or 10(a,b,n) µg EGF, or partially purified 20,000-M, preparations from P-100 columns of either TGF (1 mg; e, f) or SGF (1 mg; g,h), were added. Cultures were kept at 25 °C for 1 min, then disrupted by incubation for 1 min at 4 °C in 0.05 ml 10 mM sodium phosphate pH 7.2, 100 mM NaCl, 1% Triton X-100, 0.5% sodium deoxycholate and 5 mM MgCl $_2$ buffer. [γ - 32 P]ATP (50 μ Ci) was added and incubation continued for a further 1 min. Reactions were stopped by addition of 0.05 ml of 0.65 M Tris-HCl pH 6.7, 1.0% SDS, 10% glycerol, 2.5% 2-mercaptoethanol and 0.1% bromphenol blue, heated for 2 min at 90°C and analysed by SDS-PAGE as described elsewhere9. Molecular weight standards include ⁴C-labelled myosin (M_r 200,000), phosphorylase b (98,000), bovine serum albumin (69,000) and carbonic anhydrase (30,000).

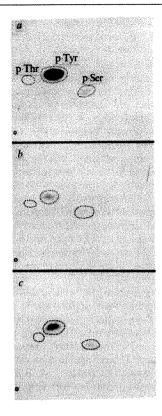

Fig. 2 Phosphoamino acid analysis of the 160 K EGF membrane receptors of A431 cells ³²P-labelled in vitro after exposure of cells to either mouse EGF or human TGF. A431 cells were incubated in medium containing mouse EGF (1 μg ml⁻¹; a) or human TGF (100 μg ml⁻¹; b), extracts prepared, and in vitro phosphorylation reactions performed as described in Fig. 1 legend. Snyder-Theilen FeSV P115 was immunoprecipitated by anti-FeLV from an extract of nonproductively transformed Fisher rat cells after labelling with [γ-³²P]ATP (c). γ-³²P-labelled proteins were recovered from gel slices by incubation in TPCK-trypsin (50 μg ml⁻¹ in 0.05 M ammonium bicarbonate, pH 8.0; Worthington) for 6 h at 37 °C. Supernatant fluids were filtered, lyophilized, washed by resuspension in H₂O and relyophilized. Tryptic peptides were hydrolysed in 6.0 M HCl at 100 °C for 1 h and two-dimensional phosphoamino acid determination performed as described elsewhere 13. The positions of unlabelled standards including phosphothreonine (p-Thr), phosphotyrosine (p-Tyr) and phosphoserine (p-Ser) are indicated by dotted circles.

 32 P-labelled P160 in extracts of either TGF(a)- or EGF(b)-treated cells contained phosphotyrosine as its major labelled phosphoamino acid, with smaller amounts of phosphothreonine and phosphoserine. Similar results were obtained for P160 isolated from extracts of SGF-treated cells. The relative proportions of 32 P-labelled phosphoamino acids in P160 after growth factor-activated phosphorylation were comparable with those found in Gardner FeSV P115 (Fig. 2c), a representative type C virus-encoded transforming protein with tyrosine-specific protein kinase activity 9 .

Although each of the growth factors examined here compete with EGF for binding to its receptor, only SGF and TGF phenotypically transform cells in culture. Analysis of the 160K EGF receptor in A431 cells by tryptic peptide mapping after either EGF- or human TGF-induced phosphorylation, revealed one major (no. 6) and seven minor phosphorylated peptides with corresponding positions, whether the tyrosine kinase was activated by EGF or by TGF (Fig. 3). On phosphoamino acid analysis of individual peptides, each was shown to contain tyrosine as its major phosphorylated species.

Cells transformed by several different RNA tumour viruses show an increase in the overall phosphotyrosine content of their proteins while those transformed by other RNA tumour viruses (mouse sarcoma, rat sarcoma)^{5,7-11,13,22} resemble the human tumour cell lines examined here in that their phosphotyrosine levels are not significantly greater than in untransformed cells. These differences may reflect the fact that viral transforming proteins encoded by avian sarcoma viruses⁵⁻⁸, Gardner and

Snyder-Theilen FeSV $^{9-11}$ and AbLV $^{12.13}$ are expressed at relatively high levels and all possess intrinsic acceptor sites for tyrosine-specific protein kinase activities. Similarly, the increase in total cellular phosphotyrosine in A431 cells in response to EGF or TGF stimulation may be due to the exceptionally large number of EGF receptors $(2-3\times10^6~{\rm per~cell})$ in the A431 cell line. Thus, the inability to detect overall increases in phosphotyrosine in most spontaneously and chemically transformed cells does not argue against a pivotal role of tyrosine phosphorylation in the maintenance of transformation of such cells.

The phenotypic response of cells to both human and mouse cell-derived TGFs is strikingly different from their response to EGF, whereas A431 cells show similar phosphorylation responses to these two classes of growth factor. It is possible that, in addition to their binding to, and phosphorylation of, the 160 K major EGF membrane receptor, TGFs interact with an unidentified TGF-specific cell receptor. Alternatively, interaction of growth factors with, and resulting tyrosine phos-

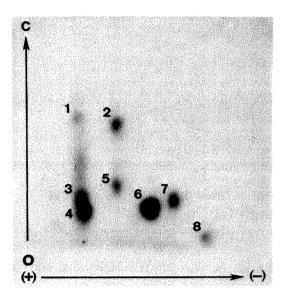

Fig. 3 Two-dimensional tryptic analysis of phosphopeptides derived from the 160 K EGF membrane receptor of A431 cells ^{32}P -labelled in vitro in the presence of human TGF. Extracts were prepared and in vitro phosphorylaton reactions performed as described in Fig. 1 legend. ^{32}P -labelled proteins were recovered from gel slices by incubation in TPCK-trypsin as described in Fig. 2 legend, then incubated for 2 h at 4 °C in 0.1 ml of chilled performic acid (30% $\rm H_2O_2$ and 90% formic acid (1:9) preincubated for 2 h at room temperature), diluted with 2 ml $\rm H_2O$, lyophilized, resuspended in electrophoresis buffer (acetic acid/formic acid/water, 15:5:80, pH 1.9) and spotted on to 10×10 cm TLC glass plates. Electrophoresis was for 30 min at 500 V and chromatography was done in the second dimension in buffer containing butanol, pyridine, acetic acid and water (32:25:5:20). Radiolabelled tryptic peptides were visualized by autoradiography.

phorylation of, the 160 K EGF receptor could be part of the pathway leading to the transformed phenotype. Minor differences in the tryptic phosphopeptide maps of the P160 receptor labelled in response to EGF- and TGF-induced phosphorylation might reflect differences in the interaction of P160 with these growth factors.

The significance of protein kinases which have specificity for tyrosine acceptor sites both in RNA tumour virus-transformed cells and in response to growth regulatory factors is not fully understood. Recent reports of a series of cellular protein kinases, which are activated by phosphorylation of tyrosine acceptor sites and in turn have specificity for tyrosine residues, may be relevant²³. Activation of this pathway leads to phosphorylation of a tyrosine regulatory site(s) on the cellular (Na⁺ + K⁺)ATPase and seems to involve the cellular analogues of certain RNA tumour viruses²⁴. It remains to be determined whether phosphorylation of cellular receptors in response to TGFs directly leads to cell transformation by activation of a phosphorylation cascade.

Somatostatin modulates effects of angiotensin II in adrenal glomerulosa zone

Greti Aguilera, James P. Harwood* & Kevin J. Catt

Endocrinology and Reproduction Research Branch, National Institute of Child Health and Human Development. National Institutes of Health, Bethesda, Maryland 20205, USA *Food and Drug Administration, Washington, DC 20204, USA

The octapeptide angiotensin II is a major regulator of the adrenal glomerulosa zone, acting both as an acute stimulus of aldosterone secretion and as a trophic hormone which increases steroidogenic enzymes and angiotensin II receptors in glomerulosa cells^{1,2}. Angiotensin II also mediates the adrenal effects of altered sodium balance, and is essential for the aldosterone response to sodium restriction3.4. However, the adrenal effects of angiotensin II are attenuated during sodium loading, suggesting that other local or humoral factors modulate its actions on adrenal glomerulosa function^{5,6}. Somatostatin, the somatotropin release inhibiting factor of the hypothalamus, has been shown to inhibit the secretion and action of several pituitary7. and non-pituitary hormones⁹⁻¹³. Because somatostatin has been found in several non-neural tissues, and seems to act as a local regulator of endocrine function, we have now examined the possibility that it may also modulate the effects of angiotensin II in the adrenal glomerulosa cell. Our studies have shown that low concentrations of somatostatin specifically inhibit the production of angiotensin II-stimulated aldosterone, and that this action is mediated by specific, high-affinity receptors for somatostatin in the zona glomerulosa.

When incubated with collagenase-dispersed rat adrenal glomerulosa cells14, somatostatin markedly inhibited the ability of angiotensin II to stimulate aldosterone formation. As shown in Fig. 1, the maximal aldosterone response to angiotensin II was reduced by 43% in the presence of 1 nM somatostatin, and was abolished by 1 µM somatostatin. In contrast, the aldosterone

responses to other stimuli, including potassium, ACTH and 8-bromo-cyclic AMP, were completely unaffected by somatostatin at concentrations of up to 1 µM. Although low concentrations of somatostatin (10⁻¹⁰-10⁻⁹ M) had no effect on basal aldosterone production, higher concentrations (>10⁻⁸ M) had a minor stimulatory effect on aldosterone production. The latter effect was inconstant and varied with the source and batch of the peptide, whereas the inhibitory effect of low concentrations of somatostatin was always evident. The inhibitory effects of somatostatin on the stimulation of aldosterone by increasing concentrations of angiotensin II are shown in Fig. 2. Without changing the basal aldosterone production, 10^{-10} and 10^{-9} M somatostatin reduced the maximal aldosterone responses to angiotensin II. Higher somatostatin concentrations (10⁻⁸ and 10⁻⁷ M) also decreased the maximal responses to angiotensin II, although basal aldosterone production was elevated due to the direct stimulatory action of the somatostatin preparation used in this experiment. Micromolar concentrations of somatostatin completely abolished aldosterone responses to angiotensin II concentrations up to 10^{-6} M.

To elucidate the mechanism by which somatostatin exerts its specific inhibitory effect on angiotensin II action, we analysed the interactions of synthetic somatostatin with adrenal receptors for angiotensin II and somatostatin. In 125 I-angiotensin II binding studies, several somatostatin preparations completely inhibited angiotensin II binding, but with varying half-maximum potencies ($\overline{\text{ID}}_{50}$) of $4.2 \pm 1.0 \times 10^{-8} \text{ M}$, $3.8 \pm 2.5 \times 10^{-7} \text{ M}$ and $5.1 \pm 1.2 \times 10^{-6}$ M for Beckman lots E0535 and B00926, and Peninsula peptides, respectively. These concentrations were similar to those required for stimulation of aldosterone production by the individual preparations, suggesting that interaction with the angiotensin receptor is responsible for their weak steroidogenic effects. This possibility was supported by the ability of the angiotensin II antagonist [Sar¹, Ala⁸]angiotensin II in three experiments (not shown) to inhibit the aldosterone responses to both 10^{-9} M angiotensin II and 10^{-7} M somatostatin, while the ACTH-stimulated aldosterone response was unchanged. The basis of the direct actions of certain somatostatin preparations on the angiotensin II receptor is not known, but such high-dose effects are not relevant to our main finding, that low concentrations of somatostatin consistently inhibit the aldosterone response to angiotensin II.

The specific inhibition of angiotensin-stimulated aldosterone responses by low somatostatin concentrations could not be explained by interaction with the angiotensin II receptor. Thus, nanomolar concentrations of somatostatin did not influence

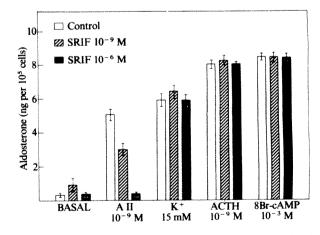

Fig. 1 Effect of somatostatin (Beckman, lot E0535) on basal and stimulated aldosterone production in collagenase-dispersed rat adrenal glomerulosa cells. Aliquots containing 1-2×10⁵ cells were incubated for 2 h and aldosterone production was determined by direct radioimmunoassay of the incubation media 14. Bars represent the mean and s.e. of three experiments. AII, angiotensin II; 8Br-cAMP, 8-bromo-cyclic AMP.

angiotensin II binding, yet significantly decreased the aldosterone responses to angiotensin II, suggesting that the peptide could act through specific receptors in the glomerulosa zone. In binding studies with ¹²⁵I-Tyr¹-somatostatin, specific highaffinity receptor sites for somatostatin were found in the adrenal capsule, which contains most of the zona glomerulosa layer (Fig. 3). In contrast, particulate fractions from the decapsulated adrenal displayed only 10% of the binding found in adrenal capsules (data not shown). In six experiments, the mean binding capacity for somatostatin was 329 ± 64 fmol per mg of adrenal capsular protein, and the association constant (K_a) was $0.9 \pm 0.3 \times 10^{10} \,\mathrm{M}^{-1}$. The binding of $^{125}\mathrm{I-Tyr}^1$ -somatostatin to adrenal capsular particles was saturable and specific, with no displacement by angiotensin II, [D-Ala⁶]gonadotropin releasing hormone, vasopressin, oxytocin and substance P, at concentrations up to 10^{-5} M. The specificity of the somatostatin receptor sites has been confirmed in studies which demonstrate that a series of somatostatin analogues displace 125I-Tyr1-somatostatin from adrenal capsular membranes with potencies that correlate with their ability to inhibit angiotensin II-stimulated aldosterone15

Somatostatin has been identified by immunofluorescence studies in specific cells of several tissues including thyroid⁹, pancreas^{11,13} and gastric mucosa^{12,13,16}, and local release of the peptide has been proposed to control the function of endocrine cells. Evidence for such a mechanism in the glomerulosa zone was sought by analysing the endogenous somatostatin content of the adrenal capsule. Tissues were homogenized in 2 M acetic acid, boiled for 5 min and centrifuged at 15,000g. The supernatant was lyophilized and the somatostatin content of the extract was determined by radioimmunoassay¹⁷. immunoreactive somatostatin in extracts from adrenal capsules was $1,817 \pm 200$ pg per mg, compared with $146 \pm 15, 7.6 \pm 1.3$ and 10.3 ± 2 pg per mg in extracts of decapsulated adrenals, urinary bladder and aorta, respectively. The values observed in adrenal capsule were comparable with those present in the pancreas and gastrointestinal tract¹², and were much higher than could be attributed to peptide binding to the specific receptor sites of the zona glomerulosa.

These data demonstrate the presence of somatostatin receptors and well defined actions of the tetradecapeptide in the

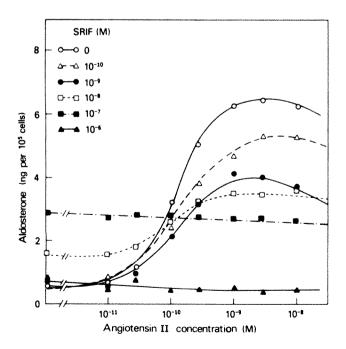

Fig. 2 Inhibition of aldosterone responses to angiotensin II (10⁻⁹ M) by somatostatin (SRIF) in collagenase-dispersed adrenal glomerulosa cells. Data points are the mean of duplicate incubations in one of three similar experiments.

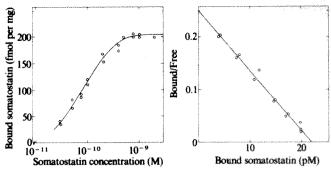

Fig. 3 Saturation curve and Scatchard plot of the binding of somatostatin (SRIF) to adrenal particles. Tyr¹-SRIF (Peninsula) was iodinated with ¹²⁵I by a modification of the technique of Hunter and Greenwood¹⁸, using prolonged incubation with low concentrations of chloramine T (1 µg). The reaction was terminated by addition of an excess of tyrosine, and the labelled peptide was purified by chromatography on a 0.7×14 cm Biogel P-2 column eluted with 0.01 M acetic acid. Specific activity of the tracer was 1,500-2,000 µCi per µg and maximum binding to excess receptors was 40-60%. Binding assays were performed by incubation of 50-100 µg of protein in 50 mM Tris-HCl buffer, pH 7.4, containing 10 mM MgCl₂, 2 mM EGTA, 20 µg ml⁻¹ bacitracin, 50 µg ml⁻¹ Merthiolate and 1% bovine serum albumin in a total volume of 500 µl. Incubations were performed for 30 min at 20 °C, and bound ¹²⁵I-Tyr¹-SRIF was separated by filtration through Whatman GF/C glass fibre filters. Nonspecific binding was determined in the presence of 10⁻⁷ M unlabelled SRIF and this value (<1% of total radioactivity added) was subtracted from total binding to yield specific binding (8-15% of the total radioactivity added). Data points are the mean of duplicate incubations from a typical experiment.

adrenal glomerulosa zone. Somatostatin specifically inhibited the aldosterone responses to angiotensin II, and this effect was manifested at much lower concentrations of the peptide than those required to inhibit angiotensin II binding. Therefore, it is likely that somatostatin exerts its inhibitory effect on angiotensin II-induced aldosterone responses by interacting with specific high-affinity receptors and modulating the second messenger system that mediates the action of angiotensin II on aldosterone biosynthesis. The occurrence of high concentrations of immunoreactive somatostatin in the adrenal capsule suggests that, as in certain other tissues, somatostatin is locally secreted and could exert a regulatory action on target cell responses to endocrine stimulation. The highly specific inhibitory action of somatostatin on angiotensin II-stimulated aldosterone production could be relevant to the changing sensitivity of the adrenal glomerulosa zone to angiotensin II during the physiological control of aldosterone secretion.

We thank Dr S. Bathena for performing radioimmunoassay of somatostatin in tissue extracts.

Gonadotropin releasing hormone stimulates calmodulin redistribution in rat pituitary

P. Michael Conn*, James G. Chafouleas†, Deloris Rogers* & Anthony R. Means†

Calcium (Ca²⁺) seems to have an informational role in many tissues. In particular, it fulfills the requirements of a second messenger for gonadotropin releasing hormone (GnRH)-stimulated luteinizing hormone (LH) release from the pituitary gonadotrope (see ref. 1 for review). Very little is known about the effect of this ion on intracellular targets or the mechanism by which Ca2+ mobilization stimulates LH release. One intracellular target for Ca2+ is calmodulin, a ubiquitous intracellular receptor that has been shown to modulate many cellular functions, including cyclic nucleotide and glycogen metabolism. protein phosphorylation, microtubule assembly and disassembly, Ca2+ flux, and the activities of NAD kinase, tryptophan 5' monooxidase and phospholipase A_2 (see refs 2-5 for reviews). We have now used a specific and sensitive radioimmunoassay to determine the quantity and distribution of calmodulin in the gonadotrope before and during GnRH-stimulated LH release. The data indicate that GnRH stimulates redistribution of calmodulin from the cytosol to the plasma membrane and suggest that the molecule may have a role in the mechanism of stimulus-secretion coupling.

Figure 1 shows the distribution of calmodulin in the subcellular fractions (expressed as a percentage of the homogenate) at the indicated dose and time after GnRH injection. There is an initial rise in the percentage of calmodulin associated with the plasma membrane which appears concomitantly with the depletion of cytosolic calmodulin. The increase occurs with a time course similar to that of secretion of LH into the blood. As the calmodulin begins to disappear from the plasma membrane fraction, its level increases first in the mitochondrial/granule and microsomal fractions and finally in the cytosol. There is also a dose-response relationship between plasma membrane accumulation of calmodulin and its cytosolic depletion (Fig. 2). Des¹GnRH²⁻¹⁰, which binds to the GnRH receptor with nearly 1,000-fold less affinity than GnRH itself⁶ and which had no efficacy in stimulating LH release in vivo, did not stimulate calmodulin redistribution (data not shown).

Calmodulin synthesis is constitutive in all systems examined (including the GnRH-stimulated pituitary)⁷. Accordingly, the redistribution reported here may indicate translocation between subcellular compartments. Accumulation of calmodulin at the plasma membrane at the expense of the cytosol might allow altered calmodulin control of regulatory functions at these loci. There is some evidence for such altered regulation by calmodulin in other systems. In the red blood cell, islet cell and adipocyte⁸⁻¹⁰ calmodulin-activated ATPases are located at the plasma membrane. In the case of the adipocyte, activation of Ca² ATPases seems to be hormonally regulated. Although calmodulin redistribution may be either a cause or a consequence of the secretory process, it does seem to have some role in secretion. Calmodulin has been found at the postsynaptic membrane, seems to mediate the Ca2+ effects on synaptic transmission 11,12 and may, accordingly, have a role in the release of neurotransmitters. In addition, trifluoperazine (Stellazine),

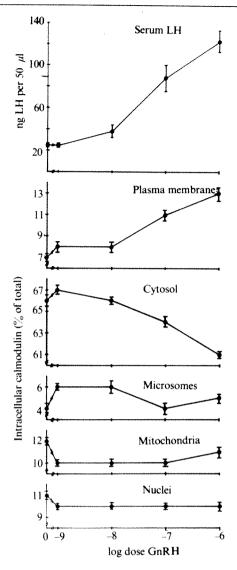

Fig. 1 GnRH concentration dependence of LH release and intracellular redistribution of calmodulin. GnRH (0.1-2 µg per rat, as indicated, obtained from the National Pituitary Agency) was administered by subcutaneous injection (0.1 ml in phosphate-buffered saline) to ovariectomized rats (Zivic-Miller, 5-7 weeks old, ovariectomized at 24 days). After 35 min the rats were killed by decapitation. Trunk blood was collected and serum LH determined by radioimmunoassay (materials from NIAMDD, standard RP1, antibody LHS-5, LH for iodination I-5, prepared by Dr A. Parlow). The assay is sensitive to < 1 ng per tube and cross-reacts < 1% with follicle stimulating hormone. Pituitaries were removed and homogenized (1 ml per pituitary) with a Dounce all-glass homogenizer (five strokes A pestle, three strokes B pestle) in ice-cold 0.5 M sucrose, 50 mM Tris-HCl pH 7.4, 25 mM KCl, 2 mM MgCl₂, 1 mM CaCl₂ (0.5 M sucrose- TKMC). The suspension was filtered through organza cloth which was further washed with 1 ml per pituitary of 0.5 M sucrose-TKMC. This filtered suspension was the homogenate fraction. After saving an aliquot for assay, the remainder of the homogenate was centrifuged at $1,000g_{\rm ave}$ for 10 min in a Beckman TJ-6 centrifuge. The pellet (P₁) was suspended by gentle homogenization (two strokes of the B pestle) in 2.0 M sucrose-TKMC and further centrifuged at 20,000 gave for 45 min (Sorvall SS-34 rotor). The pellet (P2) and supernatant were designated nuclear and plasma membrane fractions, respectively. The supernatant of P1 (S1) was centrifuged at 12,000 gave for 20 min to collect the mitochondrial/granule fraction and the supernatant of this centrifugation further centrifuged at 100,000gave (Beckman type 40 rotor) to collect the microplasmal (pellet) and cytosolic (supernatant) fractions. Aliquots of the homogenate and subcellular fractions were assayed for DNA, protein and LH or for marker enzymes (aldolase, glucose-6-phosphatase, malic dehydrogenase, NADH cytochrome c reductase and 5' nucleotidase) using previously described methods (refs 21, 22). These analyses indicated < 10% cross-contamination between fractions. Other aliquots were stored at -70 °C, then heated and assayed for calmodulin as previously reported²³. The calmodulin concentration in the homogenate was 0.56 ± 0.04 ng per μ g protein. The values shown are means ± s.e.m.

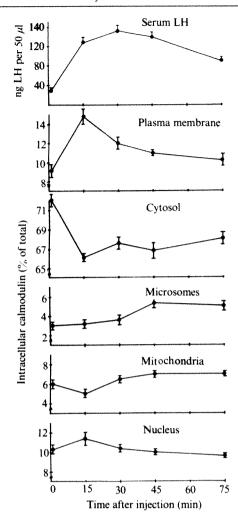

Fig. 2 Time course of LH release and subcellular calmodulin redistribution after a 2 µg injection of GnRH. Rats were killed at the indicated time. Subcellular fractions were prepared and assayed as described for Fig. 1.

which binds to calmodulin and inhibits some of its actions, also inhibits intestinal electrolyte secretion to the blood¹³

Although internalization of GnRH does not seem to be required for the release process¹⁴ the gonadotrope responses to this releasing hormone include receptor patching, capping and ligand internalization¹⁵, as observed for many cell-surface receptor-mediated systems. Recruitment of the clathrin-coated vesicles to the plasma membrane can be observed as coated pits sensitive to phenothiazine calmodulin inhibitors¹⁶ and a recent study has shown that calmodulin is a constituent of the coated vesicle¹⁷. Thus, its appearance at the plasma membrane may be associated with the recruitment of coated pits involved in the internalization process. Insulin, which is also internalized¹⁸, is associated with the translocation of glucose transport activity from the microsomal or Golgi fractions to the plasma membrane^{19,20}. Thus, the phenomena of redistribution of new activities to the plasma membrane may be a generalized occurrence for plasma membrane receptor-mediated events and suggests a mechanism by which calmodulin regulated events could be effected in the absence of additional synthesis.

This work was supported by NIH HD07053 (A.R.M.), HD13220 (P.M.C.), RCDA NIH HD00337 (P.M.C.) and the Southern Regional Educational Board (P.M.C.).

Note added in the proof: Since acceptance of this article, it has been shown²⁴ that neurotropic agents are non-competitive antagonists of GnRH-stimulated LH release. The drug concentration needed to inhibit 50% of stimulated release correlated well with the ability to inhibit enzyme activation by calmodulin

The expression-linked copy of surface antigen gene in Trypanosoma is probably the one transcribed

E. Pays, M. Lheureux & M. Steinert

Département de Biologie Moléculaire, Université libre de Bruxelles, 67, rue des Chevaux, 1640-Rhode St Genèse, Belgium

The antigenic specificity of the living trypanosome seems to be determined by the protein component of a unique glycoprotein species covering the whole surface of the parasite. During chronic infection, a single clone of trypanosomes may successively express a large repertoire of different variable antigen types (VATs). There are probably as many genes as variantspecific antigens (VSAs) (see refs 1-3 for reviews). The expression of the genes coding for the synthesis of these antigens is linked to genomic rearrangements involving duplication of the coding sequence and transposition of the additional copy The regulation of the expression of the VSA genes is operated at the transcriptional level⁷⁻¹⁰. It can thus be supposed that their transcription depends on the presence of the additional, transposed copy. We report here that this additional copy is in a chromatin configuration highly sensitive to pancreatic deoxyribonuclease, suggesting that it is the transcribed one.

The isolation of a cDNA clone coding for the AnTat 1.1 VSA of Trypanosoma brucei brucei (EATRO 1125, serodeme AnTar 1) has been described elsewhere. Detailed Pstl restriction analysis and hybridization with probes prepared from different parts of this cloned AnTat 1.1 cDNA enabled us to show that several copies of the AnTat 1.1 sequence are present in distinct bands of the genomic DNA (ref. 6 and Fig. 1). Of these, only a 6.4-kilobase (kb) and a 2-kb band seem to contain all the information present in the cDNA6 and to share a common SstI site 400 base pairs (bp) upstream of the coding sequence (Fig. 2 and manuscript in preparation); the other bands, which either contain incomplete sequences or show poor hybridization, are considered as imperfect copies of the the AnTat 1.1 gene⁶. The 3' site of all these PstI fragments is the only PstI site found in the cDNA, 340 bp from the 3' extremity (refs 6, 9 and Fig. 2). All these bands thus contain 5'-neighbouring genomic DNA as well as AnTat 1.1 information corresponding to the large (1,360-bp) 5' fragment of the cDNA. The remaining 3'-terminal Pstl sequence is not detected here, as our probe is the 550-bp HindIII-HindIII fragment (see Fig. 2). We have shown⁶ that the

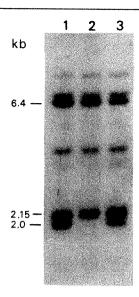

Fig. 1 Expression-linked copy of the AnTat 1.1 and AnTat 1.1b genes. The ³²P-labelled 550-bp *HindIII-HindIII* fragment of AnTat 1.1 cloned DNA was prepared as described previously^{6.9} and hybridized with Southern blots of *T. brucei brucei* nuclear DNA digested by *Psi*I. The DNA was extracted from bloodstream forms of the trypanosome expressing the VATs AnTat 1.1 (lane 1) or AnTat 1.1b (lane 3), or from procyclic forms derived from an AnTat 1.1 cloned population (lane 2) (see ref. 6 for details). The 2-kb band, which has clearly been lost in the procyclic trypanosomes, contains the additional, expression-linked copy of the VSA gene.

2-kb fragment is expression linked, being found only in the homologous AnTat 1.1 genomic DNA and not in DNA prepared from other variants of the same serodeme. The 6.4-kb Psfl fragment, present in the DNA of all the variants examined, is supposed to contain the basic copy of the AnTat 1.1 gene, that is, the one thought to be used as template to generate the expression-linked copy found in the 2-kb fragment⁶. It seems that the two copies are not contiguous, but rather that the additional copy has been transposed in a completely new genetic surrounding (Fig. 2). On the other hand, this additional copy is not extrachromosomal (data not shown). Finally, Hoeijmakers et al.⁴ have shown that the additional copy does not arise from DNA methylation of the target restriction site.

That the additional band is linked to transcription is already suggested by the fact that in all cases so far examined, a close correlation exists between the presence of the extra band and its corresponding mRNA (refs 4, 6, 9 and unpublished data). Moreover, we found that both the AnTat 1.1 mRNA and the 2-kb PstI additional band (Fig. 1, lanes 1, 3) are present in two clone populations of different lineage expressing the same AnTat 1.1 VAT (ref. 6 and manuscript in preparation). On the other hand, in procyclic forms of the trypanosome, in which the expression of the VSA is turned down¹¹, the 2-kb AnTat 1.1 additional band was not detected (ref. 6 and Fig. 1, lane 2),

although these procyclic trypanosomes were directly derived, by in vitro cultivation, from an AnTat 1.1 clone.

The only firmly established difference between active and inactive chromatin in eukaryotes is the differential sensitivity of their DNA to DNase I¹²⁻¹⁷. The transcribed sequences are indeed preferentially digested, probably because of the presence in active chromatin of either hyperacetylated histones¹⁸⁻²⁶ or some high-mobility group proteins²⁷⁻³¹. In protozoa in particular, DNase I selectively releases high-mobility group proteins from *Tetrahymena* nuclei³⁰.

We prepared nuclei from trypanosomes expressing the VAT AnTat 1.1 and submitted them to mild digestion by DNase I. As clearly shown in Fig. 3, among the AnTat 1.1-specific PstI bands, only the 2-kb additional sequence preferentially disappears

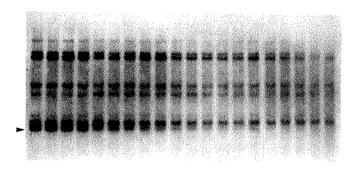

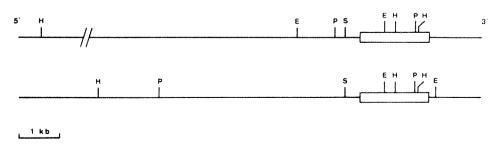

Fig. 3 Kinetics of the DNase I digestion of AnTat 1.1-specific sequences. Nuclei were purified from a clone population of trypanosomes expressing the VAT AnTat 1.1, by homogenization of the cells for 1 min at 23,000 r.p.m. in a Virtis 23 homogenizer, in 10 volumes of 0.32 M sucrose, 25 mM KCl, 3 mM MgCl₂, 20 mM Tris-HCl (pH 7.4) (medium A) at 4 °C. After centrifugation at 1,500g for 10 min the pellet was resuspended in the same volume of medium A, but with 0.2% Nonidet P40 (Shell), and homogenized by hand in a Potter apparatus. After centrifugation as above, the nuclei were washed twice in 10 mM NaCl, 3 mM MgCl₂, 10 mM Tris-HCl (pH 7.4) (medium B), then incubated at 20 °C for different periods as indicated, in 100-µl aliquots of medium B at 1 mg DNA ml⁻¹ with 80 ng ml⁻¹ DNase I (Worthington), previously freed from RNase by UMP agarose chromatography incubations were stopped by the addition of 5 volumes of 25 mM EDTA, 0.2% SDS and 250 µg ml⁻¹ proteinase K(Boehringer). After incubation for 15 h at 37 °C, the DNA in each sample was extracted by phenol/chloroform (1/1), chloroform and ultimately by ether, incubated with $200~\mu g~ml^{-1}$ RNase A (previously freed from DNase by heating for 10 min in a boiling water bath) then re-extracted as above and precipitated in ethanol at -20 °C. After centrifugation for 1 h at 16,000g, the DNA pellets were resuspended in 0.1 mM EDTA, 10 mM Tris-HCl (pH 7.5); 1 μg of each DNA sample was digested for 4 h at 37 °C with 10 units of PstI (Boehringer). The electrophoresis in 0.85% agarose gels, blotting on nitrocellulose filters, hybridization with a AnTat 1.1-specific cloned DNA probe and autoradiography were performed as described previously⁹. The different lanes contain, from left to right, a control DNA without DNase and samples incubated for 0, 5, 15, 30, 45, 60 s, 2, 3, 4, 5, 10, 15, 20, 30, 45, 60, 90, 120, 180 min with DNase. The arrow head indicates the additional band, containing the expression-linked copy of the VSA gene.

Fig. 2 Restriction maps of the basic (bottom) and additional (top) copies of the AnTat 1.1 gene and of their neighbourhood. Digestions with restriction endonucleases and hybridization of Southern blots of total genomic DNA digests with AnTat 1.1-specific probes were performed as described elsewhere E = EcoRI; H = HindIII; P = PstI; S = SstI. The 5' HindIII site to the left of the additional

copy is located 19 kb from the next *Hin*dIII site in the AnTat 1.1 coding sequence. The putative extent of the coding sequence (1,700 bp, see ref. 9) is indicated by an open box.

after DNase I treatment. Because of their larger target size, the largest bands are affected on long DNase exposure. However, despite its larger size, the 6.4-kb PstI fragment thought to contain the basic AnTat 1.1 sequence seems, among others, to be considerably less degraded than the expression-linked copy. If bands of similar size are compared, such as the 2.15- and the 2-kb fragments, the differential sensitivity to DNase I is particularly evident.

The chromatin of trypanosomes has not been extensively

studied, but seems to be organized in typical nucleosomes 32,33 and to be made of the same histones as other eukaryotes³³. It can thus be reasonably assumed that in trypanosome nuclei also, the transcribed sequences are preferentially digested by DNase I. It is concluded that the additional, expression-linked copy of the VSA gene, which is in a chromatin configuration highly sensitive to DNase I, is most probably the one which is transcribed.

Structure of mouse metallothionein-I gene and its mRNA

Niall Glanville, Diane M. Durnam & Richard D. Palmiter

Howard Hughes Medical Institute Laboratory, Department of Biochemistry, University of Washington, Seattle, Washington 98195, USA

Metallothioneins are small cysteine-rich proteins that bind heavy metals such as zinc, cadmium, copper and mercury^{1,2}. Recent interest in these proteins has focused on the part they play in zinc metabolism and heavy metal detoxification1. Our interest in metallothionein genes stems largely from the observations that these proteins are inducible by both heavy metals and glucocorticoid hormones^{1,3}. To explore the regulation of these genes, we have isolated cDNA and genomic clones corresponding to mouse metallothionein-I (MT-I)4, and have used them to show that both inducers act at the transcriptional level in vivo and in a wide variety of cell lines⁵⁻⁸. We have also shown that the MT-I gene is amplified during selection for cadmium resistance⁵. To investigate the mechanisms of gene regulation, knowledge of the primary DNA sequence is necessary. Here we present the entire sequence of mouse MT-I gene along with ~300 bases of 5' flanking region that presumably includes promoter and regulatory sites. The 5' mRNA sequence, defined by S₁ nuclease mapping, was combined with sequences of the coding and 3' untranslated regions obtained previously to allow a computer prediction of the most stable secondary structure of MT-I mRNA.

The sequence of the mouse MT-I gene and its flanking regions is shown in Fig. 1a. Sequencing was done using the Maxam-Gilbert method9 with the strategy illustrated in Fig. 1b. Comparison of the genomic sequence with that of the cDNA clone⁴ shows that the coding region of the gene is interrupted by two introns as predicted by heteroduplex mapping4. The three exons of the gene are indicated by large capitals in Fig. 1a while the introns and flanking regions are shown by small capitals. The intron-exon junctions were deduced by comparing the genomic and cDNA sequences. Both introns obey the GT-AG rule originally proposed by Breathnach et al. 10—they start with the dinucleotide GT and end with AG. In addition, both have a 3

polypyrimidine tract similar to the polypyrimidine regions identified in many other introns¹¹. In many genes, introns lie between functional domains of the encoded protein 12-14. However, the 20 cysteine residues of metallothionein which coordinate seven metal atoms into two domains15 are distributed throughout the molecule (Fig. 1a), making it difficult to assign functional domains to the three exons.

The 5' end of exon 1 was deduced by S₁ nuclease mapping¹⁶. Total RNA isolated from cadmium-resistant Friend erythroleukemia cells was hybridized to a probe generated by cutting a plasmid carrying the genomic MT-I gene at its unique BgIII site (position +64, Fig. 1a) and labelling the 5' ends with 32 P. After S₁ nuclease digestion, the size of the resistant fragments was analysed by comparing it with a sequencing ladder of the Bg/II-AvaII fragment (+64 to -180, Fig. 1a). The results, shown in lane 1 of Fig. 2, indicate that the most abundant DNA fragment generated by S₁ nuclease comigrates with the G labelled +1 in Fig. 1a. Control experiments in which either MT-I mRNA or S₁ nuclease was omitted showed no DNA bands migrating in this region (lanes 2 and 3, Fig. 2). The concensus sequence, Y-C-A-Y (in which the A is position +1; Y represents unspecified pyrimidine nucleoside), derived from comparisons of 20 mRNA start sites¹⁷ is located three nucleotides downstream from the G labelled +1 in Figs 1a and 2. Perhaps steric hindrance from the mRNA cap structure retarded S₁ nuclease digestion of our DNA probe down to the last base-paired nucleotide. We obtained the same result when the S₁ nuclease digestion was done at either 37, 50 or 60 °C. This analysis indicates that the 5' end of exon 1 and the mature mRNA lies 74 nucleotides from the coding region of MT-I mRNA.

Analysis of the region 5' to exon 1 shows that, like many other eukaryotic genes that are transcribed by RNA polymerase B, there is a Goldberg-Hogness (TATAAA) sequence (boxed in Fig. 1a) located between nucleotides -23 and -28. The sequence GC_CCAATCT, which is also common to various eukaryotic genes 18, is not present in the 5' flanking region of the MT-I gene. The 5' region does, however, contain two large palindromic sequences centred at positions -55 and -103(underlined in Fig. 1a). We are now generating mutants in this region to determine which areas are involved in the regulation of MT-I gene expression.

Localization of the mRNA start site allowed us to write the complete sequence of MT-I mRNA (Fig. 3). Computer

Fig. 1 The DNA sequence of the MT-I gene. a, Sequencing was done by the method of Maxam and Gilbert⁹. Exons are shown in large print; introns and the regions flanking the gene are shown in small print. The sequences of commercially available restriction enzymes that recognize 6-base pair (bp) sequences are underlined and named. Possible regulatory sites at the 5' end of the gene as discussed in the text are also underlined. The TATAAA sequence, initiation and termination codons are boxed. The MT-I protein sequence is indicated above the exon sequences using the one letter code: A, Ala; C, Cys; D, Asp; G, Gly; K, Lys; M, Met; N, Asn; P, Pro; Q, Gln; S, Ser; T, Thr; V, Val. b, Sequencing was done from the restriction sites indicated. DNA fragments were either³² P-labelled at the 5' end using T4 polynucleotide kinase or at the 3' end using the large subunit of DNA polymerase I. Many of the sequence segments were determined on both DNA strands; all the sequence was analysed at least twice.

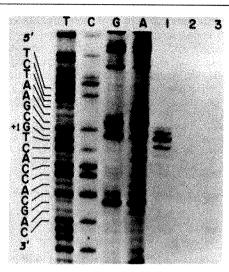

Fig. 2 Localization of the metallothionein-I mRNA start site by S₁ nuclease mapping. Lanes T, C, G and A: sequencing ladder from the Bg/II site (+64 in Fig. 1a). Labelling of the lanes from the sequencing gel has been transposed so that the mRNA sequence can be read directly. Lane 1, S1 nuclease-resistant products obtained by digesting a hybrid between a DNA probe labelled at the Bg/III site and MT-I mRNA. A genomic clone was digested at the unique BgIII site, treated with alkaline phosphatase, and labelled with $[\gamma^{32}P]ATP$ using T4 polynucleotide kinase; the specific activity of the probe was 4×10^6 c.p.m. per pmol of 5' ends. The probe was treated with proteinase K and phenol-chloroform extracted. Aliquots $(4 \times 10^5 \text{ c.p.m.})$ were ethanol-precipitated with 140 µg of total RNA from cadmium-resistant Friend erythroleukemia cells⁵ (35 ng of MT-I mRNA). The precipitate was dissolved in 25 µl of 80% formamide, 0.4 M NaCl, 40 mM PIPES buffer (pH 6.5), 1 mM EDTA, overlaid with paraffin oil, heated at 80 °C for 5 min and incubated at 50 °C for 12 h. The samples were then diluted 10-fold with 10 mM Tris-HCl, pH 7.5 and ethanolprecipitated. The nucleic acids were dissolved in 25 µl of 10 mM NaCl and then 2.5 µl of buffer containing 3 M NaCl, 300 mM NaOAc, 30 mM ZnOAc, pH 4.5 was added. S₁ nuclease (2 μ l, prepared by the method of Vogt²¹) was added and the sample incubated at 60 °C for 40 min. An aliquot (1 µl) was loaded onto the sequencing gel. Lane 2, conditions were the same as for lane 1, except that 140 µg of chicken calvaria RNA was hybridized with the probe. Lane 3, same as lane 1 except that no S₁ nuclease was added. A high-molecular weight band representing undigested ³²P-labelled DNA was visible on the gel but is not shown.

analysis 19 of this sequence showed that various similar secondary structures were possible for MT-I mRNA. The most stable secondary structure predicted is shown in Fig. 3. This structure has an overall free energy of -87 kcal, suggesting that it is fairly stable. The model shows that most of the MT-I coding region, including the initiation codon (AUG), is contained within the duplexed region of the molecule, whereas the stop codon (UGA) is exposed in a loop. Note that the positions where RNA splicing occur (arrows, Fig. 3) are located very close to each other at the base of loop structures. It has been suggested that genes may evolve by addition or subtraction of exons²⁰. In order for this mechanism to yield a functional protein, the reading frame of the exons as well as a stable secondary and tertiary structure of both the protein and its mRNA must be preserved. Inspection of the secondary structure model of MT-I mRNA (Fig. 3) shows that the absence of exon 2 would have little effect on mRNA secondary structure. In addition, the reading frames of exons 1 and 3 are preserved without exon 2 (Fig. 1a). Thus, a plausible model for the evolution of MT-I gene might involve the primordial existence of an uninterrupted gene consisting of the nucleotides now represented by exons 1 and 3. This gene might then have been interrupted by an intron into which exon 2 was later inserted. Cell transformation techniques should allow us to reverse this process as a way of testing the hypothesis of exon addition.

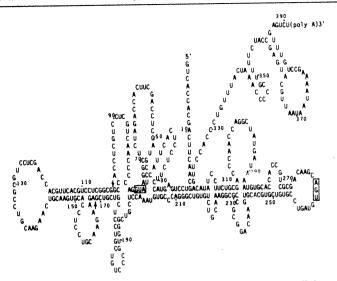

Fig. 3 Computer model of the secondary structure of MT-I mRNA. Analysis was done using the computer program developed by Pipas and McMahon¹⁹. The initiation codon (AUG) and the termination codon (UGA) are boxed. Splice points are indicated by arrows.

We thank Drs R. Gelinas, T. Gingeras and J. Millazzo for help with the computer analysis of MT-I mRNA secondary structure, and Ms Abby Dudley for secretarial assistance. This work was supported by NIH grant HD-09172. N.G. was a fellow of the Jane Coffin Childs Memorial Fund for Medical Research.

Recombination between short **DNA** homologies causes tandem duplication

Thomas Edlund & Staffan Normark

Department of Microbiology, University of Umeå, S-901 87 Umeå, Sweden

The ampC gene of Escherichia coli K-12 codes for a B lactamase which can hydrolyse the β -lactam ring of ampicillin^{1,2}. Ampicillin resistance is strictly related to ampC gene copy number thus we have been able to isolate ampicillin-resistant mutants carrying multiple ampC repeats3.4. We have isolated on a plasmid a segment of chromosomal DNA carrying multiple ampC repeats, and compared the nucleotide sequence of the region joining repeat units to the sequence of the DNA segments that fused to create the joint. The fusion had occurred within a 12-base pair (bp) sequence of perfect homology. We suggest that recombination between randomly occurring short homologies (12-13-bp long), could be a general mechanism to generate tandem duplications in the size range of 10 kilobases (kb).

The properties of E. coli K-12 mutants carrying multiple copies of the ampC gene have been described elsewhere^{3,4}. We isolated amplified mutants that were derivatives of an ampC up-promotor mutant resistant to ~20 μg ml⁻¹ ampicillin⁵. By reciprocal recombination between a ColEl-ampC hybrid plasmid, pNU1 (ref. 4), and the chromosome of two ampCamplified mutants, plasmid derivatives were isolated which carried multiple copies of the respective ampC duplication. One of these, derivative pNU8, carried multiple ampC genes of repeat size 9.8 kb. The repeat was found to have both its end points within the chromosomal DNA carried by plasmid pNU1 (ref. 4) thus plasmid pNU8 could be used as a source of DNA for the segments involved in the formation of the novel joint in the 9.8-kb repeat. The only difference between restriction fragment patterns obtained for pNU1 and pNU8 was the presence of an additional joint fragment in the latter. The restriction enzyme PvuII was used to generate a length of DNA small enough for sequence analysis but which also carried the joint fragment. Figure 1 shows the PvuII sites on plasmid pNU1. We concluded that the 9.8-kb repeat of pNU8 had one end point in the PstI4-PvuII5 fragment (fragment A) and the other in the PvuII₉-Pst₁ fragment (fragment B) of pNU1. Thus, the PvuII joint fragment (fragment C) of pNU8 consists of parts of fragments A and B.

The strategy for sequencing relevant stretches in fragments A, B and C is described in Fig. 2 legend. By comparing the sequences of these stretches (Fig. 3), it was found that the two DNA segments that had recombined contained a 12-bp long sequence of perfect homology, which was also present within the novel joint of fragment C. Thus, the 9.8-kb duplication had occurred by a recombination event at some point within these 12-bp sequences of fragments A and B.

E. coli strain Gllal is usually resistant to 20 μg ml⁻¹ of ampicillin. Mutants of Gllal resistant to 40 or 60 µg ml⁻¹ of

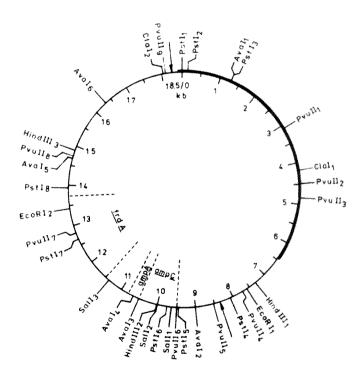

Fig. 1 Physical restriction fragment map of plasmid pNU1. The location of the ClaI and PvuII sites within pNU1 were determined by double digestions with these enzymes and the enzymes previously used to map pNU1 (ref. 4). The restriction endonuclease cleavage sites are numbered, starting from the PstI1 site at the top. The thick-lined segment represents DNA from ColE1. Arrows indicate the end points for the 9.8-kb repeat unit. Locations are given for the frdA and ampC genes as well as the ampA control region.

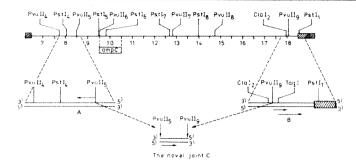

Fig. 2 Strategy for sequencing the novel joint of the 9.8-kb repeat, and the DNA segments involved in its formation. The numbered solid line at the top represents chromosomal DNA carried by plasmid pNU1. Hatched areas represent ColE1 DNA. The box indicates the position of the β -lactamase structural gene, ampC. The TaqI site within the PvuII₉-PstI₁ fragment was located by the mapping technique of Smith and Birnstiel⁸ using purified $ClaI_2$ -AvaI₁ fragment of pNU1. For this purpose the fragment was end-labelled at the ClaI 5' terminus. The PvuII₅-PvuII₉ fragment carrying the novel joint was purified from plasmid pNU8 whereas the other fragments sequenced were from pNU1. Arrows indicate the direction and extent of sequencing runs, using the Maxam-Gilbert method⁹.

Fig. 3 Comparison of nucleotide sequences within fragments $Pst_4-PvuII_5$ (A) and $PvuII_9-PstI_1$ (B) of pNU1, and the PvuII 'joint' fragment (C) of pNU8. Boxed nucleotides represent a 12-bp perfect homology present in all three fragments. In fragment A this sequence was located ~90 bp from the $PvuII_5$ end, and in fragment B 230 bp from the $PvuII_9$ end. A recombination event within these 12 bp produced the novel joint.

ampicillin were isolated; this level of resistance corresponds to that shown by defined mutants carrying an amp duplication or triplication. By further selection for ampicillin resistance, amplifiable derivatives resistant to between 600 and 1,000 µg ml⁻¹ of ampicillin were obtained from individual Amp⁻⁴⁰ or Amp⁻⁶⁰ clones. Ten amp-amplified mutants were isolated in this way. The sizes and end points of their respective repeat units were determined by cleavage of chromosomal DNA with restriction endonucleases and the fragmentation patterns compared with that of pNU1. This ColE1 hybrid plasmid carries 12 kb of chromosomal DNA surrounding the amp gene. The

Table 1 Effect of size of homology on the length of DNA required to contain expected numbers of homologies

Homology		No.	of homolo	gies	
size (bp)	1	4	9	16	25
10	2*	3	4	5	6
11	3	5	7	9	11
12	5	9	13	17	21
13	9	17	25	33	41
14	17	33	49	65	81

Calculations were based on the fact that in a random sequence the number of homologies are proportional to the square of the length of the DNA segments expected to contain homologies.

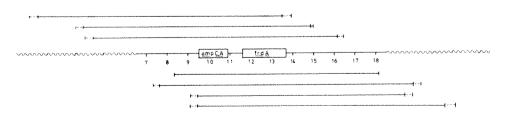

* The sizes of DNA fragments are given in kilobase pairs.

repeat copy number of the mutants was from 30 to 50 as judged from their ampicillin resistance, allowing restriction fragments of repeated chromosomal DNA larger than 400 bp to be detected. The sizes and end points of the respective repeats are given in Fig. 4. The end points could be accurately determined for seven amplified mutants; none of these had the same two end points. The sizes of the repeats varied between 9 and 13 kb. The remaining three mutants carried larger repeats (~18 kb). However, as their end points were situated outside the chromosomal DNA carried by pNU1, it was not possible to determine their exact position. However, we concluded that the end points of the ten different repeats were all located within 20 kb of chromosomal amp DNA.

A similar ampicillin selection procedure was performed on a recA1 derivative of Gllal. Chromosomal DNA from 15 independently isolated Amp^r-300 derivatives was digested with several restriction endonucleases. No amplified fragments were observed in any of the mutants. These results suggest that the frequency of generation of amp duplications is decreased in a recA1 background to such an extent that other types of ampicillin resistant mutants will predominate after the selection. On average, two homologous 12-bp sequences of any composition will be found within a random DNA sequence of 4 kb. This was deduced from the equation $x^2 = 4^n$, where n is the number of homologous base pairs and x is the number of base pairs which should contain a duplicate of any composition of n base pairs in length. This equation is an approximation which is valid if $x \gg n$.

In the *amp* system duplications may not occur within the *ampC* gene, which constitutes about 1 kb. Thus, on average, a duplicate of any 12-bp sequence will be found once in 5 kb. The general formula for this system will therefore be $(x-1,000)^2 = 4^n$. The size of *amp* DNA required for different numbers of homologies with sizes ranging from 10 to 14 bp is given in Table 1; twenty-five 12-bp homologies and nine 13-bp homologies would be expected within a 21-kb and a 25-kb random sequence, respectively. In addition, our sequence and distribution data suggest that unequal recombination between any homologies close to 12 bp may be a general mechanism for

Fig. 4 Distribution of amp repeats in seven independent Amp^r mutants of E. coli K-12. The size and end points were determined by cleavage of chromosomal DNA with a series of restriction endonucleases. The amplified fragments were compared with the fragmentation patterns of plasmids pNU1 and pNU8. The

numbered solid line indicates chromosomal DNA carried by pNU1; wavy lines represent surrounding chromosomal DNA. Horizontal bars above and below the genetic map indicate the extent of different amp duplications. Dashed lines indicate the extent to which the respective end point was mapped. The approximate locations for the ampC and the frdA genes are indicated by boxes. A represents the control sequence region for ampC.

generating tandem duplications. Our results also suggest that recombinations between such small homologies are promoted by the recA protein.

The novel joint described here was formed by recombination between DNA segments carrying a 12-bp perfect homology but with no other obvious homologies. This implies that the opportunity to form stable base pairing is an important feature of the mechanism that gives rise to tandem duplications. Promoter structures and possibly other controlling sequences which exist in many copies on the bacterial chromosome, could provide homologies for duplication, thus allowing catastrophic deletions. However, available sequence data on promoters indicate that they have been built up to contain recognition regions only a few base pairs long, interrupted by non-homologous stretches of nucleotides⁶. This strategy should prevent recombination and thus avoid deleterious deletion. In fact, it has been shown that intragenic deletions within the lacI gene can occur at repeated sequences as short as 5 bp?

Temperature-dependent ΔC_p^0 generated by a shift in equilibrium between macrostates of an enzyme

Harvey F. Fisher, Alan H. Colen & Richard T. Medary

Laboratory of Molecular Biochemistry, Department of Biochemistry, University of Kansas School of Medicine and the Veterans Administration Medical Center, 4801 Linwood Blvd, Kansas City, Missouri 64128, USA

Substantial negative heat capacity changes $(\Delta C_n^{\theta'})$ have frequently been observed to accompany the formation of protein-ligand complexes^{1,2}. Glutamate dehydrogenase³ and horse liver alcohol dehydrogenase4, however, have been reported to form binary complexes with coenzyme with negligible $\Delta H^{0\prime}$ and only small ΔC_{ν}^{0} s. Although many intriguing mechanisms have been proposed to account for the observed phenomena, there is little direct experimental evidence available which might provide a basis for evaluating the contributions of ΔC_p^{0} s of complex formation from the various mechanistic sources or even for distinguishing between them. However, if, as Eftink and Biltonen⁵ have suggested, a shift in equilibrium between macrostates contributes significantly to an observed $\Delta C_p^{0\prime}$ for a given reaction, it should be possible to characterize such a system by measuring the temperature dependence of the ΔC_p^{0} . Despite this, few studies have determined ΔH^{0} values at more than two temperatures. We have now measured the temperature dependence of the ΔH^{0} (and, thereby, that of the ΔC_{p}^{0}) of the formation of an enzyme-reduced coenzyme complex in an attempt to provide such a basis and have found that the entire $\Delta C_p^{0\prime}$ of complex formation is accounted for by a temperatureinduced shift of an equilibrium between the different forms of the free enzyme.

The temperature dependence of the calorimetrically measured ΔH^{0} for the reaction written as

$$E+NADPH \rightleftharpoons E-NADPH$$
 (1)

is shown in Fig. 1. Although the free enzyme is stable up to a temperature of ~50 °C (ref. 6), the E-NADPH complex is markedly more heat-labile,7 and reliable measurements of the formation of this complex cannot be made at temperatures above 35°C using attainable flow rates. Precautions and controls described in Fig. 1 legend, however, assure us of the validity of measurements up to 35 °C.

If the formation of the E-NADPH complex proceeded according to reaction (1) unaccompanied by a measurable ΔC_i^c the data of Fig. 1 would lie on a horizontal straight line, because $(\partial \Delta H^{0i}/\partial T)_p = \Delta C_p^{0i}$. If the reaction proceeded with finite temperature-independent ΔC_p^0 , the data would lie on a straight line with a slope equal to ΔC_p^0 . It is apparent from Fig. 1 that the data correspond to neither simple case. The plot shows a marked curvature, the $\Delta C_p^{0'}$ approaching 0 at low temperatures and increasing to a value of -450 cal K⁻¹ mol⁻¹ at higher temperatures. This behaviour can be explained on the basis of a temperature-sensitive equilibrium between 'implicit' macrostates of at least one reaction component⁸.

Consider a binding reaction which is thought to be expressed by reaction (1) but which, in fact, involves the following equilibria:

$$\begin{array}{c|c}
E' \\
\kappa_2 \parallel \\
NADPH + E & \rightleftharpoons E-NADPH
\end{array}$$
(2)

where

$$K_2 = \frac{[E]}{[E']}$$
 and $K_1 = \frac{[E-NADPH]}{[E][NADPH]}$

We assume that neither step involves a measurable ΔC_p . If step 2 is itself accompanied by a substantial ΔH^{0i} , and has a ΔG^{0i} such that $K_2 = 1$ within or near the experimental temperature range, the observed ' $\Delta H^{0\prime\prime}$ ' for reaction (1) will vary from $\Delta H_1^{0\prime}$, the value at temperatures at which the protein is entirely in the E form, to a value $(\Delta H_1^{0\prime} + \Delta H_2^{0\prime})$, at temperatures at which the protein is entirely in the E' form. By definition, the resulting temperature dependence of ΔH^{0i} will be interpreted as a ΔC_p^{0i} effect; and, if measurements are performed over a sufficient range of temperatures, the ΔC_p^{0r} itself will be found to be temperature dependent. This will be so even if, as we have assumed, both $\Delta H_1^{0\prime}$ and $\Delta H_2^{0\prime}$ are themselves temperature independent. We have portrayed the ligand as binding to only one form of the enzyme for ease in following the argument. In practice, no such distinction can be made from equilibrium measurements.

The dependence of ΔH^{0} on temperature for reaction (2) is

$$\Delta H^{0i} = \Delta H_1^{0i} + \frac{\Delta H_2^{0i}}{1 + K_2}$$
 (3)

where $K_2 = \exp[\Delta H_2^{0'}(T - T_2)/RTT_2]$ and T_2 is that temperature at which $\Delta G_2^{0'} = -RT \ln K_2 = 0$.

The solid line in Fig. 1 shows the best fit of equation (3) to the data with the parameters $\Delta H_1^{0\prime} = 4.73 \pm 0.28 \text{ kcal mol}^{-1}$, $\Delta H_2^{0\prime} = -20.1 \pm 2 \text{ kcal mol}^{-1}$ and $T_2 = 43.6 \pm 1 \,^{\circ}C$. The magnitude of the apparent ΔC_p^0 generated by the effect of

varying temperature on this implicit equilibrium is8

$$\left|\Delta C_p^{0r}\right| = \left|\left(\frac{\partial \Delta H^{0r}}{\partial T}\right)_p\right| = \frac{K_2(\Delta H_2^{0r})^2}{(1 + K_2)^2 R T^2} \tag{4}$$

For a reactant isomerization (such as reaction (1)), the sign of ΔC_p^{0r} is negative. For a reaction sequence involving a product isomerization step, however, the sign of ΔC_p^{0} is positive.

In Fig. 2 we have plotted ΔC_p^{0} as a function of temperature according to equation (4) using the best-fit parameters and algebraic sense of Fig. 1.

Because the sign of the ΔC_p^{0} is negative, if there is a single (implicit) isomerization in the overall reaction, it must involve one of the reactants rather than one of the products. An attempt to fit the data to an equation similar to that for reaction (2) expanded to include an isomerization of the E-NADPH complex as well as one of E, indicated no contribution from that added feature. Thus, although there may be an isomerization of the enzyme-ligand complex, evidently such an equilibrium either is not poised in or near the experimental temperature range or must not involve a substantial ΔH^{0} . As reaction (2) is symmetrical in E and NADPH, an isomerization of the ligand could account for the data as well as an isomerization of E. While NADPH is known to exist as an equilibrium mixture of folded and unfolded forms, the T_2 for this process is below 20 °C and its ΔH^{0} is too small to make an appreciable contribution to the observed process9. The attempted inclusion of finite intrinsic ΔC_p^{0} terms for steps 1 and 2 of reaction (2) also failed to improve the fit of the equation to the data.

We conclude, therefore, that the observed ΔC_n^{0} of the formation of the glutamate dehydrogenase-NADPH complex is fully accounted for by a poised isomerization of the free enzyme involving a very large enthalpy change that is largely compensated by an opposing large entropy change, the step in itself

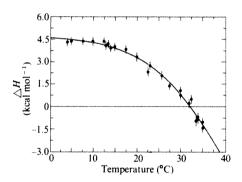

Fig. 1 The temperature dependence of ΔH^{0} of the glutamate dehydrogenase-NADPH complex in 0.1 M phosphate buffer, pH 7.6. The reaction heats, q, were determined in a flow microcalorimeter using apparatus, reagents and procedures as previously described³. The enzyme concentration was usually ~90μM (active sites). At each temperature, calorimetric measurements were made at saturating concentrations of NADPH starting at 20 × KD and extending to $200 \times K_D$. A plot of q versus [NADPH] was linear with a slope of $0 \pm 6 \times 10^{-4}$ kcal per mol NADPH in each case. As noted in the text, while the free enzyme is stable at 50 °C, its reduced coenzyme complex denatures rapidly above 37 °C. The following controls and precautions assure us that the data presented are unaffected by errors due to denaturation. (1) The solution emerging from the calorimeter was assayed for enzymatic activity. The activities so measured agreed with those of the initial solution to within 5% and showed no trend indicating denaturation. As the solution remains at an elevated temperature for some time after leaving the sensing chamber of the instrument, any time-dependent denaturation would be magnified several-fold by the time the solution actually emerged from the instrument. (2) The value of q was unchanged on raising the flow rate from 10 μ ls 13 μ ls $^{-1}$. Had there been any significant time-dependent do . Had there been any significant time-dependent denaturation, the value of q would have differed because the two flow rates correspond to different residence times. The solid line is calculated from a nonlinear least-squares fit to reaction (3). The ΔH^{0} , value at 15 °C differs from that reported prevously using a batch calorimeter. The batch value (and the very small ΔC calculated from it) must now be presumed to be erroneous.

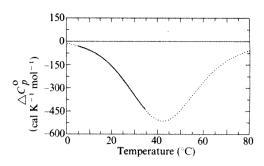

Fig. 2 The temperature dependence of ΔC_p^{0} of the glutamate dehydrogenase-NADPH complex. The line is calculated from equation (4) using parameters from Fig. 1. The solid line portion of the curve indicates the region covered by experimental data.

involving no detectable $\Delta C_p^{0\prime}$ and H⁺ transfer to or from the buffer not contributing significantly to the measured enthalpy change.

A similar mechanism, involving a temperature-induced shift between multiple forms of the free enzyme, is consistent with the recently reported large ΔC_p^{\dagger} in the glutamate dehydrogenase-catalysed reaction⁸. We cannot say how general the phenomenon reported here may be, but we note that ΔC_p^{0} s reported for complexes of other dehydrogenases at 20 °C are of a similar magnitude to that of glutamate dehydrogenase at its maximum near 40 °C. Thus, the differences between the ΔC_p^{0} s of the various enzymes may simply reflect differences in the T_{2} s of otherwise similar mechanisms.

Corrigendum

In the letter 'Competition relatedness and efficiency' by J. R. W. Harris, Nature 292, 54-55, the parameter x in equation (2) should be replaced by z.

Errata

In the article 'Seismotectonics of the El Asnam earthquake' by M. Ouyed et al., Nature 292, 26-31, the legend to Fig. 6 was reproduced incorrectly in some copies of *Nature*. It should read: a, The 1.30-m left lateral slip measured on a ploughed field at Zebadja near the centre of the fault. b, Southern segment of the fault. Typical pressure ridges showing the uplift of the northwestern block (to the left), and collapse due to gravity. Extension cracks follow the compression axis.

In the news item 'Yugoslavian nuclear power: Locals late reacting', Nature 291, 446, the name of the head of the Croatian Commission for the Human Environment was given incorrectly. It should read Marko Branica.

MATTERS ARISING

Grand unification magnetic monopoles inside the Earth

CARRIGAN1 has suggested that the equilibrium between the magnetic and gravitational forces would lead to these monopoles being trapped in two positions on the magnetic axis, one each side of the centre, depending on their polarity. However, his discussion is incorrect in several respects. First, in the Earth's core, the gravitational field is roughly proportional to radius r. If the magnetic field were due to a central dipole it would be proportional to r^{-3} , and there would be (radial) equilibrium on the axis at $\sim r =$ $0.18 R_{\rm e}$, within the fluid core, as he states. But the magnetic field is far from being dipolar, and within the core the dipole and non-dipole fields are comparable in magnitude; even at the core surface there are already ~14 positions2 where the field is radial, not just the two he assumed.

Second, in fact, the magnetic field is produced by electric currents in the core; reasonable current distributions give a dipole radial component of field which increases only very slowly with depth. This would give an 'equilibrium' radius of $\sim 0.007 R_{\odot}$ only 50 km from the centre, and well within the solid inner core. Third, 'equilibrium' calculations apparently considered only radial forces, and for his dipole 'equilibrium' the monopole is unstable to infinitesimal tangential displacements. Stable equilibrium would require complicated fields with a most unlikely coincidence of magnitude and topology.

Finally, as Carrigan points out, in the core there are probably toroidal fields much larger than the poloidal dipole fields. However, these toroidal fields have no radial component, and will be largely latitudinal, so will not "result in large axial fields". What they will do is make it even less likely that there will be any stable positions of purely radial field. The inner core also will have large toroidal fields³.

It does seem most unlikely that there will be any significant trapping of monopoles by the mechanism Carrigan suggests.

CARRIGAN REPLIES—Because of the limitations of space I could not emphasize the model nature of the calculation. However, I did point out that the dipole

model was not a proper picture of the interior of the Earth. I did not say a monopole of one polarity would occupy a single region of equilibrium but rather that GUMMs of one polarity would interchange with those of the other polarity. I did not touch on one aspect of the situation, the fact that GUMMs would probably not move rapidly through solid material in the interior of the Earth. If this is so it represents a third effective force. Static or dynamic equilibrium would be a result of all three effective forces.

In view of the limits of the picture—little is known about GUMM energy loss processes, there is incomplete knowledge of the interior of the Earth and little understanding of the accretion mechanism—it did not seem appropriate to develop a more comprehensive picture. The main point I wished to make was that even a relatively few GUMMs of opposite polarities could contribute a spectacular amount of energy.

RICHARD A. CARRIGAN JR

Fermi National Accelerator Laboratory, PO Box 500, Batavia, Illinois 60510, USA

Estimated speed of a giant bipedal dinosaur

FROM observations of locomotion in diverse living animals, including ostrich, bird, man, horse and elephant, Alexander obtained a relationship between speed, stride length (λ) and body size (expressed by h, height at the hip). This relationship seems to hold true, at least in general terms, for large and small animals, both bipeds and quadrupeds, at gaits from walk $(\lambda/h < 2.0)$ to run $(\lambda/h > 2.0)$. To estimate the speeds of certain dinosaurs Alexander applied this relationship to their tracks, where λ could be measured directly and h could be estimated from the size of the footprints. He found that the estimated speeds were rather low—between 1.0 and 3.6 m s⁻¹ (3.6 and 13.1 $km h^{-1}$).

Alexander's method has since been applied to various other dinosaur tracks²⁻⁵, but few of these have yielded speed estimates greater than about 4.2 m s⁻¹ (15.0 km h⁻¹). A notable exception was provided by Russell and Béland², who calculated that a short section of trackway in the Mesaverde Formation (Cretaceous) of Colorado⁶ had been made by a dinosaur running at a speed of 7.54 m s⁻¹ (27.1 km h⁻¹). The Colorado dinosaur was apparently a giant bipedal ornithischian (probably an ornithopod of the family Hadrosauridae), with h being

~3.44 m and a live body weight of ~11 tonnes2. Russell and Béland based their calculations on data published by Brown⁶, whose account of the Colorado trackway is rather ambiguous; in one place Brown referred6 to a "fifteen foot stride", while in another he mentioned that the dinosaur "stepped 15 feet 2 inches". A stride is commonly understood to comprise two consecutive steps, or paces7, though the terms 'stride' and 'step' have sometimes been used synonymously. Evidently Brown was referring to a step (or pace), for the distance of 15 feet was measured between two footprints which identified as those of left and right feet. Russell and Béland apparently followed Brown's interpretation: they presumably took the figure of 15 feet to represent a step (left footprint to right footprint) and doubled it to obtain the figure of 9.25 m which they cite for stride length²

I have examined photographs of the Colorado footprints (supplied by Dr E. S. Gaffney), and I suspect that Brown's interpretation of them may be wrong (see Fig. 1). The two footprints identified by Brown as left and right are very similar,

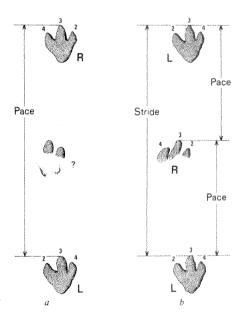

Fig. 1 Diagram illustrating two interpretations of ornithopod dinosaur trackway from the Cretaceous of Colorado (American Museum of Natural History, no. 3650). Each footprint has the digits numbered and is identified as left (L) or right (R). The footprints are represented by natural casts on the under-surface of a sandstone bed, so that left and right appear transposed. a, Brown's interpretation⁶, indicating a pace of ~15 feet (4.57 m); the surface feature marked? is not regarded as part of the trackway. b, Revised interpretation, indicating a pace of ~7.5 feet (2.29 m).

and they may well be prints of the same (left) foot. Both prints seem to show the same pattern of asymmetry-weak outward curvature of digit 3, and an angle of divarication between digits 2 and 3 which is slightly greater than that between digits 3 and 4. Mid-way between these two footprints is a poorly defined surface feature which was regarded by Brown⁶ as an amalgam of two footprints from other dinosaur tracks. This feature is probably an incomplete print of the ornithopod's right foot; it is about the same width as the other two footprints and shows traces of three digits with an appropriate pattern of divarication. The three footprints have a pattern of digit spacing (digit 2 slightly more divergent than digit 4) which is characteristic of many ornithopod footprints5 and which is consistent with their identification as left, right and left. This interpretation also reveals distinct positive (medial) rotation of the footprints, an arrangement which is common in the trackways of other bipedal dinosaurs (see, for example, refs 8 and 9); no such footprint rotation is evident in Brown's interpretation.

According to the revised interpretation (Fig. 1b) Brown's measurement of 15 feet would actually represent a stride (between successive prints of the same foot). Using Alexander's method¹, it may then be calculated that the Colorado ornithopod was walking (with λ/h of 1.34) at a speed of 2.4 m s⁻¹ (8.5 km h⁻¹). The highest speeds so far estimated from dinosaur tracks are in the region of $3.6-4.3 \text{ m s}^{-1}$ (13.0-15.5 km h⁻¹), and these are attributed to small bipedal runners with h < 1 m (refs 1,5). There are no reports of tracks indicating that larger bipedal dinosaurs were capable of achieving a running gait (with $\lambda/h >$ 2.0).

I thank Dr E. S. Gaffney (American Museum of Natural History) for providing a description and illustrations of the Colorado footprints.

RUSSELL REPLIES—Brown clearly uses 'stride' in the sense of step in his description1: "The tracks... (show) the right and left foot in normal stride where the giant

had stepped 15 feet". He also describes a third footprint, made when the animal had stepped on a firmer substrate. The steps defined by the three footprints would presumably have been of comparable length or Brown would not have referred them to the same trackway. In view of the symmetry of hadrosaur footprints² and Brown's presence at the site where the trackway was excavated, prudence suggests that his interpretation remains as plausible as Thulborn's proposed alternative.

Inhibition of haemoglobin S gelation and water structural effects

BENESCH AND BENESCH¹ recently proposed an interesting hypothesis concerning the mechanism of action of various hydrophobic molecules which inhibit the gelation of sickle cell haemoglobin (HbS). They suggested that this hydrophobic class of sickling inhibitors may act on water structure rather than interact directly with HbS. The physical explanation provided by Benesch and Benesch¹ for the 'melting' of the HbS gel at low temperatures seems very plausible. They suggest that the creation of more polyhedral void spaces in water at lower temperatures and the consequent coalescence of 'filled' (with nonpolar moieties) and 'empty' polyhedral cages is responsible for weakening the hydrophobic forces. However, they extend this reasoning to suggest that the inhibition of polymerization of HbS by a variety of compounds containing hydrophobic residues is also "brought about by competition between the water polyhedra filled with small hydrophobic molecules and those attached to the protein, rather than a direct interaction between the hydrophobic residues and the protein which should be stereospecific". The two situations are not physically analogous.

The clumping of 'empty' and 'filled' polyhedral cages leads to the relief of hydrophobic interactions while clumping of filled cages with other filled cages produces hydrophobic interactions2. This will apply equally whether the cages are filled with nonpolar segments from the protein or the small hydrophobic molecules. When the latter are added to a solution containing the HbS polymer, some existing water polyhedral void spaces will be further occupied and the resulting encounter of cages filled with small hydrophobic molecules with those filled with nonpolar side chains of the protein should provide the stimulus for a direct (hydrophobic) interaction of the small molecule with the haemoglobin nonpolar side chains, in competition with the side chain-side chain interaction. Gel melting can occur, in such cases, by a substitution of protein-protein hydrophobic interaction with protein-small molecule hydrophobic interaction. This interaction may be weak or strong, depending on the nature of the molecule and the side chain. If, in addition to this hydrophobic interaction, ionic or hydrogen bonding is possible, the direct interaction will be further strengthened. Such a possibility has been postulated for a molecule like benzyl alcohol³, although there has been no direct proof of this.

The attempts to increase the effectiveness of hydrophobic antisickling agents by structural modifications have failed so far. not because the agents are incapable of direct interaction with the protein but because of stronger macromoleculemacromolecule interactions in the polymer.

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 500 words and the briefest of replies, to the effect that a point is taken, should be considered. Proceedings of a Conference held 1—3 September 1980 in Grignon, France

Liposomes, Drugs and Immunocompetent Cell Functions edited by Claude Nicolau and Alain Paraf

August/September 1981, xiv + 194pp., £14.00 (UK only)/\$34.00, 0.12.518660.6

The chapters of this volume reflect the multidisciplinary nature of the meetings by discussing liposome research from a number of different angles. The main topics considered are the physico-chemical properties of liposomes and their design, the use of liposomes to transport molecules into a variety of cells, the improvement of their stability, the use of virus envelopes to introduce material into cells, immunological targeting of liposome and transmembrane signalling via membrane bound enymes. In discussing these topics, the contributors not only reappraise existing knowledge but also present new findings. Areas of new research covered include the transfer of genetic material, the use of liposomes in vivo and in vitro and targeting with monoclonal antibodies.

Genetic Engineering 2

edited by Robert Williamson

July/August 1981, xii + 204pp., £9.80 (UK only)/\$24.00 (Paper), 0.12.270302.2

The second volume of this important serial publication contains four long contributions from leading researchers in the field. Like the first volume, Genetic Engineering 2 presents up-to-date reviews of current research rather than detailed descriptions of practical aspects.

A.J. Jeffreys: Recent studies of gene evolution using recombinant DNA. H.H. Dahl, R.A. Flavell and F.G. Grosveld: The use of genomic libraries for the isolation and study of eukaryotic genes. A.D.B. Malcolm: The use of restriction enzymes in genetic engineering. J.D. Beggs: Gene cloning in yeast.

Rhône — Poulenc Round Table Conferences

The Future of Antibiotherapy and Antibiotic Research

edited by L. Ninet, P.E. Bost, O.H. Bouanchaud and J. Florent

July/August 1981, xx + 508pp., £25.00 (UK only)/\$60.00, 0.12.519780.2

The purpose of the Rhône-Poulenc Round Table Conferences is to bring together a number of widely known scientists from universities and the pharmaceutical industry who are engaged in common research. The second conference was held in Paris in February 1980, and was an attempt to obtain a fully up-to-date assessment of the most important aspects of the use and development of antibacterial agents. Its proceedings are contained in the present book, which comprises 31 chapters by 44 leading experts.

The Geology of Libya

Volumes 1, 2 and 3

edited by M.J. Salem and M.T. Busrewil

July/August 1981

Volume 1: xiv + 348pp., £20.00 (UK only)/\$48.00, 0.12.615501.1 Volume 2: xii + 430pp., £20.00 (UK only)/\$48.00, 0.12.615502.X Volume 3: xi + 338pp., £20.00 (UK only)/\$48.00, 0.12.615503.8

The symposium of which these volumes are the record — held in Tripoli in Al-Fateh University, September 1978 — was the second of its kind to be held on the subject. Since the first, in 1969, so many new data and ideas have come to the fore that it has become essential to be able to find in one place a complete survey of the decade's work on every aspect of Libya's geology. The three volumes of this major treatise provide just that, including in their scope stratigraphy and biostratigraphy, palaeontology, sedimentation, hydrology and hydrogeology, Quaternary geology and geomorphology, petroleum geology, mineralogy and economic geology, igneous petrology, structural geology and geophysics.

Cancer Research in the People's Republic of China and the United States of America

Epidemiology, Causation and New Approaches to Therapy edited by Paul A. Marks

January 1981, 288pp., £13.80 (UK only)/\$24.50, 0.8089.1363.8 (Grune & Stratton)*

From the Preface: The first bilateral Conference on cancer research in the People's Republic of China and the United States was held at Columbia University on the fifth anniversary of the opening of the University's Comprehensive Cancer Center and the Julius and Armand Hammer Health Science Center. This volume is composed of those papers delivered by scientists who participated in this conference . . . The Conference occurred at a time when advances in the study of cancer epidemiology, biology and therapy in the laboratories of both nations are offering new options for the prevention as well as the treatment of cancer. These timely and useful substantive exchanges among scientists working in these areas of cancer research in our two countries have enabled us to provide detailed reports of data, in several instances previously unpublished, that can be utilized by our colleagues around the world, who are working to decrease the burden of cancer in our

New Land for Old

The Environmental Renaissance of the Lower Swansea Valley

S J Lavender

The illustrated case-study of the environmental reclamation of a region once described as 'the most concentrated and uninterrupted area of industrial dereliction in Britain'. It outlines the causes and extent of the despoliation and pollution, the unique interdisciplinary study of the Lower Swansea Valley Project, and the subsequent programmes of reclamation and community involvement. The book is published during the current European Campaign for Urban Renaissance, sponsored by the Council of Europe; the Lower Swansea Valley exemplifies the themes of this campaign, and their relevance to the reclamation of all derelict urban land.

Two new titles in the series Medical Physics Handbooks:

9: Physics and the Circulation J O Rowan

Describing for the first time in a single publication the various methods used to investigate the circulation of blood in the human body. It is hoped that this integrated presentation will enable physical and clinical scientists to appreciate better the relative merits of the different methods and to match the most appropriate technique to each clinical application. The first two chapters discuss the general properties of blood, hydrostatics applied to the vascular system, and haemodynamics. The remaining chapters describe in detail the basic principles and measurement techniques associated with each of the different methods, identifying their limitations and potential sources or error, and discussing their respective clinical applications.

July xii+125 pp 215×155 mm illus hardcover 0-85274-508-7 £11.95

10: The Evaluation of Medical Images

A concise introduction to the field of image assessment and its application to medical imaging systems. The text progresses from an account of the formation and physical properties of images to a discussion of how the diagnostic medical image conveys information beneficial to the health care of the patient. Techniques are described for the evaluation of images and the extraction of quantitative information from them, prior to a consideration of the overall efficacy of imaging systems. Efforts to measure a 'figure of merit' for an imaging system are discussed, providing an insight into the difficulties of image assessment using physical criteria, coupled with a realisation that a diagnostic image is useful only if it alters the treatment of the patient. Principles and Instrumentation — A.T. Marshall; Preparation of Specimens: Changes in Chemical Integrity — A.J. Morgan; Frozen-Hydrated Specimens — A.T. Marshall; Frozen-Hydrated Sections — A.T. Marshall; Sections of Freeze-Substituted Specimens — A.T. Marshall; Influence of Specimen Topography on Microanalysis — F.D. Hess; The Skeletal Muscle — M. Sjostrom; Liquid Droplets and Isolated Cells — J.V. Bonventre, K. Blouch and C. Lechene; Quantitative X-Ray Microanalysis of Bulk Specimens — F.D. Ingram and M.J. Ingram; Quantitative X-Ray Microanalysis of Thin Sections — G.M. Roomans; Index.

This is the first book dealing exclusively with x-ray microanalysis of biological specimens. It not only presents the basic theory and operation of the instruments used for producing, measuring and interpreting x-ray signals, but also describes in detail the preparation of bulk specimens, sectioned specimens and fluid specimens.

The book includes both qualitative and quantitative analysis of biological materials and it discusses application of x-ray microanalysis to pathology, physiology and cytochemistry.

Instrumentation is presented in a concise manner and methodology in detail. Almost all instruments are covered, including TEM, SEM and STEM. Instructions are given on how to produce, measure and interpret x-ray signals and emphasis is given to the aspects of instrumentation that are of practical use. In its comprehensive compilation of methods for preparing biological specimens the advantages and disadvantages of alternate methods are discussed.

READERSHIP: Electron Microscopy, Biology, Biochemistry.

LEVEL: Undergraduate and graduate students, researchers and research technicians.

BOOK REVIEWS

Food aid, self-sufficiency and the new technology

Barbara Huddleston

In Seeds of Plenty, Seeds of Want, Andrew Pearse sets the stage for consideration of a number of new directions for food and agriculture policy in the 1980s. What to do about food aid is one of them. The subject is currently embroiled in controversy, much of it created by the uneven income distribution effects of Green Revolution technology, which food aid has more often than not reinforced.

How did food aid come to be what it is, and what changes can we expect in its use as an instrument of foreign policy and consequent impact on developing Third World economies? For answers to these questions, the interested reader should surely not miss Mitchel Wallerstein's new book, Food for War — Food for Peace. His is, however, a historian's book, and the book of a political scientist more interested in the forces which influence the level and allocation of food aid flows than in those which affect its impact on development.

Wallerstein's book is divided into four parts and 12 chapters. Part I presents a fairly straightforward, factual summary of the origin and subsequent evolution of US food aid policy and Part II does the same for other bilateral donors and the UN system. An important insight growing out of the historical material on US policy is the perception that in periods of crop surplus domestic agricultural policy concerns have dominated the political process, whereas in periods of shortage foreign policy concerns have prevailed. This means that if agricultural experts are correctly reading future trends, and world grain markets do not return to a situation of chronic surplus, foreign policy considerations will be even more important than before in fixing the level and direction of US food aid flows.

Economic development in friendly Third World countries has been and will continue to be an important objective of American foreign policy, and food aid will probably continue to be an important instrument for attempting to achieve this aim among others. In Part III, Wallerstein presents case material for each major recipient country, showing how the food aid programme had served one or more of the following foreign policy purposes: to give economic support to Cold War allies; to secure military bases; to exercise diplomatic leverage in tense international hotspots; to maintain friendly relations with UN voting allies. He also discusses the

Seeds of Plenty, Seeds of Want: Social and Economic Implications of the Green Revolution. By Andrew Pearse. Pp.262. ISBN 0-19-877150-9. (Clarendon/Oxford University Press: 1980.) £7.50, \$22.50. Food for War — Food for Peace: United States Food Aid in a Global Context. By Mitchel B. Wallerstein. Pp.312. ISBN 0-262-23106-9. (MIT Press: 1980.) \$30, £18.60.

interaction between the use of food aid to foster US trade interests and the withholding of it as a factor in US economic and commercial relations with Third World countries. An important aspect of Wallerstein's treatment is his focus on the individual concerns and policy interests of each of the four Presidents who have exercised control over US food aid policy since the shift toward its greater use for foreign policy purposes in the early 1960s. The effect of personality and temperament was clearly important, and this suggests that while the categories Wallerstein uses may be appropriate for the specific circumstances of the past, they will not necessarily fit the future so neatly.

The final part of the book treats issues relating to the role of multilateral versus bilateral food aid in the context of international politics. There are some cogent reasons for both donors and recipients to prefer that some portion of the overall flow of food aid be channelled through multilateral assistance agencies. However, both international politics and the sluggishness of the US bureaucracy constrain the amount which can be effectively administered in this way. An alternative for the future which Wallerstein suggests, and which is already a glimmering in the eyes of some of the more forwardlooking participants in the food aid debate, would be for the International Wheat Council to play an increased role in the coordination of food aid flows, and for donors to come together more frequently through aid consortia for agricultural development. This mechanism would encourage the working out of the respective roles of food aid and other foreign assistance in complementary and developmentally effective fashion, without requiring donors to give up the foreign policy benefits they stand to gain from maintaining bilateral food

programmes.

Like many good historians, Wallerstein uses his material to weave a story which is full of complexity and detail, bringing into focus the pattern of past events without prejudging the future. In a sense, Pearse's book is also historical, although he tries so hard to be true to the results of each piece of research which he reports that the story he has to tell suffers somewhat. While it is not an easy book to read, Seeds of Plenty, Seeds of Want does have some important points to make. It is a book about smallness versus largeness, about cultivation for a livelihood versus cultivation for a profit, about the old way of doing things versus the new. It raises issues and suggests problems arising out of Green Revolution strategies of agricultural development which concern aid donors and recipients

Pearse's volume grew out of a joint undertaking of the UN Research Institute for Social Development/UN Development Programme (UNRISD/UNDP) which he directed, the brief of which was to examine the socio-economic effects of the Green Revolution. The work began in 1970 and was conducted by a number of researchers, each working on an individual case study or particular aspect of the subject. Much of the research was completed by 1974 and many of the case-study results have subsequently been published in their own right. Nevertheless, the project directors rightly felt that an analytical and interpretative summary of the main conclusions and their policy implications would be in order, and Pearse's book is the result.

Since the volume is a summary of previously published reports of individual research efforts, some of them dating back several years, its analysis and conclusions do not always reflect the latest results available; nor is reference made to similar kinds of studies done by workers who were not part of the UNRISD study. This is unfortunate, since some later work modifies and amplifies the findings of the early UNRISD pieces, and the book would have had more general value if it had set the UNRISD material in the context of the larger body of work which addresses questions relating to the impact of Green Revolution technology and means of improving its effectiveness as a tool for agricultural development. Even among those who originally contributed, there is growing recognition that, as the full effects of new technologies continue to work themselves out, dynamic changes are beginning to occur which will provide new economic opportunities and more widely distributed income growth than previously thought.

This difficulty does not detract from the main thrust of the argument, however. Pearse states frankly that his objective, and that of his collaborators in the UNRISD studies, is "to strengthen those forces likely to press for non-elitist development" (p.219), and the concluding part is particularly successful in creating the basis for doing this. The first two parts attempt to draw generalizations from the specific case studies that were part of the UNRISD project. Here Pearse meets with less success — the material is organized somewhat arbitrarily around a number of themes commonly associated with Green Revolution impact analysis. However, some of the studies are quite situation specific and of doubtful general relevance.

In Part III the critical issues are summarized in Pearse's own words, and here both the nature of specific difficulties and the lines of possible policy change are spelled out with great clarity. It is not simply that the rich are getting richer and the poor poorer. More importantly, the economics of agricultural development are such that the most effective techniques for increasing agricultural production result in a reduction in welfare for small farmers where there is land scarcity and labour surplus. Pearse does not oversimplify and make the mistake of asserting that a return to subsistence agriculture can solve the food problem; he recognizes that production growth cannot occur without commercialization of farming. But he points out that under the early Green Revolution strategy, the number of sublivelihood households increased, with no comparable increase in alternative earning opportunities for the growing number of landless labourers.

Thus he recommends the different strategy of concentrating on the poor but aspiring farmer as initial adopter of new agricultural technologies, and focuses on questions of appropriateness of technologies, institutions, and price and planning policies for implementing such a strategy. Out of the questioning of the old approach and the recognition of previous failures has arisen a new "food systems" approach to planning which some countries are already beginning to pursue and which is being supported by further research at UNRISD. With its focus on the distributional as well as the yield-increasing results of agricultural development strategy, the new approach promises to open up different avenues for seeing and doing which give hope that one day a book such as this will no longer be necessary.

Barbara Huddleston is a Research Fellow at the International Food Policy Research Institute, Washington DC.

Astronomical, in content and in effort

Michael Salt and Joseph Needham

Chung-Kuo Ta Pai K'o Ch'üan Shu (The Greater Encyclopaedia of China). Vol.1 T'ien Wên Hsüeh (Astronomy). Pp.650. (Greater Encyclopaedia of China Publishing House, 1-A Wai Guan Dong Jie, Beijing, 27 (Peking), China: 1981.) \$30.

"Your writing's grown weedier and weedier:
Produce more, or we've no further need o' ya",
His publishers warned.
Their advice wasn't scorned:
He's at work on an encyclopaedia.

At the present time we seem to be flooded with encyclopaedic compilations. Last year, there was the new *Britannica*, and the 16-volume *Dictionary of Scientific Biography*. This year has seen the new and revised edition of *Grove*. In popular astronomy alone, half-a-dozen different compendia are available.

But China is different, for there has been no grand encyclopaedia produced in that great culture in modern times at all. The present book is the first of 80 volumes that will cover archaeology, law and jurisprudence, history, literature, philosophy, religion, economics and many other subjects. It deals not only with contemporary astronomy but also with its history. Astronomy is one of the few sciences for which it is possible to write a single, continuous, historical account reaching from antiquity to the present day, as was done by R. Wolf in his Handbuch der Astronomie; ihrer Geschichte and Litteratur of 1890. Now Chang Yü-Chê and his 20 colleagues have accomplished the same.

Physically, this first volume is of excellent quality. The binding (of our hardback copy, at least) has survived the destructive testing to which so many Chinese books succumb in transit; the paper is thin but substantial; and the print is clean and easy to read. The numerous intext photographs and diagrams, too, are of admirable quality. So are the beautiful coloured plates, clustered together at intervals throughout the book. Several hours of serious reading have revealed only two misprints, though in a volume of one and a half million (Chinese) characters, there must presumably be others. But our first and enduring impression is that proof-readers and publishers have done their utmost to ensure an accurate text, handsomely presented.

On the whole, the book is easy to use. An English index to entries rescues those whose technical Chinese is insufficient to give them accurate bearings in the vastness of the field. A glossary of proper names, in Roman and Cyrillic scripts, promises help with the transliterated scientists who feature in the text. This promise is not per-

haps fully carried out, however, for several names (e.g. de Broglie, Lorentz, Narlikar and Planck) are not given in the glossary. This list is really a conversion table from the Western forms to the Chinese forms, and one has to be forewarned that in the main index the alphabetical order follows the Chinese form of the name, not the original Western one. It is a pleasure to see that due credit is given to the great scientific men such as Chang Hêng, Tsu Ch'ung-Chih, I-Hsing and Kuo Shou-Ching, who figure in the history of astronomy; though we cannot say we like the practice of giving entirely imaginary portraits of them (as in Pl.5), recalling the Renaissance busts of Aristotle and Galen with which the older historians of biology and medicine used to ornament their books. There are also plenty of plates and text-figures showing ancient Chinese instruments, and pages of old Chinese books, all well explained, but they do not in any way impede the exposition of the most modern theories and the most recent knowledge. Finally, starmaps identify the traditional Chinese constellations in terms of those used scientifically today.

There are minor inconveniences. One of these arises from the purely alphabetical arrangement of the entries, which follows the sounds of the Pin-yin romanization. Another concerns the diagrams. In a work arranged by subject, a few well-placed and well-chosen diagrams can be made to serve an entire section, but here diagrams are sometimes lacking in places where they would be helpful. For instance, in the article on relativistic cosmology (p.444), there is no diagram to illustrate the different values of k in the three models of the Universe; but a suitable graph is given in the entry on the age of the Universe (p.519). Unfortunately, though, there is no crossreference.

Cross-references to entries within the volume are achieved by a simple convention; a different Chinese type-face in the text. In practice, though, this is not rigorously applied. For instance, the entry on the "problem of the advance of Mercury's perihelion" (p.333) mentions Le Verrier and Newcomb, but fails to indicate that each of these men is himself the subject of an entry (pp.204, 244).

The matter of entries leads to two more important questions. First: in an encyclopaedia of astronomy, how much physics, say, or mathematics, should be included? Second: how much background knowledge, and what level of understanding, should the compiler expect of his readers? These questions face every author. But for the encyclopaedist, they are of paramount importance.

As regards coverage, we are not competent to judge whether or not all the growing points of this prolific subject are

adequately covered. We were, however, slightly disappointed to find no separate articles on quantum theory, on the special or general theories of relativity, or on tensor analysis. One wonders why such topics as these are not separately expounded when the scintillation counter (p.288), photoneutrino processes (p.96) and metric (p.64) each feature individually? Future volumes will no doubt supply the missing information, but for the present our thirst for understanding is not slaked.

The second question is also difficult to answer on the basis of the present volume. In general, the articles are well written. Some, indeed, are admirable, both in exposition and content. Others are less good, either failing to link the subject in hand with cognate subjects, and with the general principles involved; or attempting to cover basic theory, the history of the subject and its interrelations, all in one and the same exposé. Moreover, not all articles start from the same intellectual baseline. In one, for instance, π and G are glossed, but in another, a partial differential equation is

given, without preliminaries or explanation. This case suggests that this volume is intended primarily for scholars and research workers. But if so, why do most of the articles lack bibliographies? And why are such references as are given always to books rather than to research papers?

But these are early days. We must not focus disproportionately on comparatively minor shortcomings. Subsequent volumes will surely make further improvements even on the high standard that this first volume has set. This work is of a very high standard, quite dazzling in production. Contributors and editors alike should rightly feel proud of all that they have achieved within three years. We look forward eagerly to the remainder of what promises to be a magnificent compilation.

Michael Salt and Joseph Needham are at the East Asian History of Science Library, Cambridge, UK. The most recent of Dr Needham's volumes in the series Science and Civilisation in China was published late last year.

Prehistoric Sahara of green and plenty

Martin Williams

Prehistory of the Eastern Sahara. By F. Wendorf and R. Schild. Pp.414. ISBN 0-12-743960-9. (Academic: 1980.) \$65, £24.20.

DEFUNCT lakes and rivers, plant and animal fossils, Neolithic villages and rock paintings testify to when the Sahara was, in certain parts at least, a green and pleasant land. Nowhere is the contrast between present wasteland and prehistoric plenty more stark than in the Western Desert of Egypt. For six seasons, from 1972 to 1977, a multidisciplinary team from Egypt, Poland and the United States laboured to reconstruct the life-style, economy and habitat of the Palaeolithic and Neolithic peoples who once inhabited the now-arid wastes between Libya and the Nile.

The book opens with a short, clear account of field and analytical methods. Four profusely illustrated chapters detail the archaeological finds and stratigraphy in each of the localities studied, after which the geographically and chronologically discrete strands are woven into two rich tapestries depicting the former environments and human exploitation of the Western Desert. A lucid, thoughtprovoking discussion of the origin of food production in northern Africa concludes the main section of the book. Ten specialist appendices follow, including evaluations of Quaternary deposits (marred by the unreadable Figure A1.1), radiocarbon dating problems, artefact and pottery analyses, the fossil record, and a scanning electron microscope study of cereal grains.

What conclusions emerge from these new data? The most interesting, best documented evidence relates to the Terminal Palaeolithic and Neolithic sites near Gebel Nabta, 100 km west of Abu Simbel. At Nabta playa three Holocene lake phases date to ≥ 9000 , ≥ 8600 and 7000-5800 BP. Terminal Palaeolithic sites persist until the end of the first moist phase; Neolithic sites appear at the close of the ensuing dry phase. Early cattle, sheep and goat remains date respectively to 9300, 8100 and 7000 BP. Attempts by the early desert dwellers to adapt to an increasingly harsh Holocene climate culminated in domestication of animals and plants over a thousand years before food production became widespread in the adjacent Nile valley.

The final exodus of Neolithic herders from the dying grasslands and shrinking lakes of the Saharan interior must have had repercussions beyond the confines of the desert. In this context, the recent migrations of starving herds and emaciated nomads during the latest sahel drought reflect the tragic but inexorable late Holocene desiccation of our greatest desert.

A fine testimonial to the dedication of the archaeologists and to the organizational skills of the two authors, this clearly written, well-produced volume deserves to be widely read by prehistorians and students of the Quaternary.

Martin Williams is Associate Professor in Earth Sciences and Director of the Quaternary Research Unit at Macquarie University, Australia.

Blossoming Balkans

P.J. Grubb

Flowers of Greece and the Balkans: A Field Guide. By Oleg Polunin. Pp.592 + plates. ISBN 0-19-217626-9. (Oxford University Press: 1980.) £40, \$125.

THE latest in Oleg Polunin's series of illustrated guides to European plants is a most attractive introduction to the Balkan flora, which is the richest in Europe, amounting to more than 5000 species. Over 500 of these are illustrated in colour photographs and some 350 others in blackand-white drawings. The plan of the book is essentially the same as that adopted in the earlier Flowers of South-west Europe (OUP, 1973), produced jointly with B.E. Smythies. There is a general account of the climate, geology, flora and vegetation, an introduction to each of the "plant hunting regions", and then brief diagnoses of about 2000 species (320 pp.), followed by indexes of names and places, and an exhaustive bibliography. A new departure is the index of popular names used in Yugoslavia, Bulgaria and Greece. There are 22 absolutely superb colour plates of representative landscapes, but my copy lacks numbers 1 to 4 — an unreasonable fault in a book costing £40!

The author conveys his "feel" for the country and his enthusiasm for the plants very well. His accounts of particular regions have been vetted by local botanists, and those of the several areas I have visited myself ring true. The drawings are excellent, and the photographs constitute the usual mixture, some being of little value for critical identification but others are perfect. Whether the accounts of genera that are nowhere illustrated will be of any use to those who have not seen the plants concerned elsewhere, I doubt.

The weakest part of the book is the ecological account, particularly the section on forest and scrub communities, and it would have been better to have followed more closely the scheme of Horvat, Glavac and Ellenberg, whose map of vegetationtypes has been used as the basis for the simplified map lining the covers. More precise thumb-nail sketches of the ecology of each species described would also have been possible. The worst fault is the emphasis on 1920s' ideas of "migration routes" of plants, and the failure even to mention the appreciation built up in the 1960s and 1970s of the dramatic changes that occurred in Mediterranean communities during the Ice Ages, when steppe seems to have replaced much of the forest.

Despite its minor blemishes, this book will be an invaluable guide in the Balkans for those who already have a good knowledge of northern and central European plants.

P.J. Grubb is a University Lecturer in Botany at the University of Cambridge.

Life of an archaeologist extraordinary

Peter Warren

The Find of a Lifetime: Sir Arthur Evans and the Discovery of Knossos. By Sylvia L. Horwitz. Pp.278. ISBN 0-670-13575-5. (Viking: 1981.) \$14.95. To be published in the UK in October by Weidenfeld & Nicolson, price £9.95.

FEW subjects could be more compelling for a biographer than Sir Arthur Evans. The reasons for this are not simply external: his passionate devotion, based on deep historical study and extensive topographical research, to the freedom of the Slav peoples; his re-foundation, almost creation, of the Ashmolean Museum; his virtually personal discovery of the Minoan, Bronze Age civilization of Crete, with its complex yet graceful society; and his wealth, so generously given over to recreating the Minoans for all the world. All these stand as beacons for any biographer. But what gives the subject a yet stronger appeal is the astonishing range and quality of Evans's mind, that of a true Renaissance man, as learned and appreciative in numismatics, botany, Balkan topography and history, folklore, Belgic and Roman settlement in Britain, as in Minoan archaeology.

Yet one turns to a new biography with some trepidation, since this work was done in a most perceptive and scholarly way by Joan Evans in Time and Chance (Longman, Green, 1943), published within two years of Evans's death at the age of ninety. As Sir Arthur's half-sister, Joan Evans had access to - indeed was an intimate part of - family history, which made her book a masterpiece. Since that time, too, the archaeologist W.A. McDonald has included a lengthy chapter on our subject in his excellent survey, Progress into the Past. How, then, does Sylvia Horwitz fare? The answer is that hers is very good and sympathetic account. While its lighter tone and air of a rapid read mean it in no sense replaces Time and Chance, its qualities are clear. It is accurate, a few smallish errors apart; it is lively and enjoyable, clear though brief on archaeological and Balkan political issues; it does not disguise Evans's autocratic and imperious attitudes, nor his generosity. The most perceptive sections are those examining the effects upon Evans of the death of his mother when he was six, of the sister closest to him and of his wife Margaret, daughter of the Liberal and historian Edward Freeman, after only 15 years of marriage. The author's suggestions are convincing, that these losses made Evans deeply withdrawn and much more reticent about personal feelings than was usual even for a high Victorian, while at the same time, in pursuing his scholarly and political interests, and with children, he was extrovert, generous and always vigorously engaged.

The book makes good use of the 40 years

since Evans's death and the publication of Time and Chance by describing how his theories and interpretations have fared after two more generations of archaeologists and Cretan discoveries. With the exception of his views on Mycenae, the huge edifice of thought he erected, on religion, art, architecture and Cretan prehistory, remains the firm basis of contemporary Minoan understanding. While reaction to his Minoan colonization of the Greek mainland was natural, given the rich vein of Mycenaean discoveries explored by A.J.B. Wace and a distinguished line of Greek archaeologists, the extent of Cretan artistic and economic influence throughout the south Aegean and southern Peloponnese now appears to be much greater than critics of Evans's views could then allow. His dating of the destruction of Knossos as a palace, at around 1400 BC, and all that that means for Aegean prehistory, came under detailed attack from Professor L.R. Palmer some years ago; but a large majority of archaeologists has confirmed the essential correctness of Evans's and his assistant Mackenzie's views. Thermoluminescence dating may one day provide a close date for the burning of the Linear B tablets, at the heart of that controversy, in the fire which consumed the palace.

Unlike recent studies on Schliemann, Sylvia Horwitz's account is thoroughly

Sir Arthur Evans — a true Renaissance man.

sympathetic. She admires the vast nervous energy, the astonishing yet repeated flair for understanding an object or its function from exiguous evidence, often confirmed years later by new discoveries. She found no need for a severe critique of this eminent Victorian. Her account can be warmly recommended, for itself and as a preliminary to *Time and Chance*. We should recall only that as much is to be found of political reporting from remote Bosnian fastnesses or richly flowered Ragusan gardens as of the splendours of the House of Minos.

Peter Warren is Professor of Ancient History and Classical Archaeology at the University of Bristol, and currently Director of Excavations at Knossos.

Ordered amino acids brought to book

Linda Fothergill

Handbook of Protein Sequence Analysis: A Compilation of Amino Acid Sequences of Proteins with an Introduction to the Methodology. 2nd Edn. By L.R. Croft. Pp.628. ISBN 0-471-27703-7. (Wiley: 1981.) £38, \$104.50.

This second edition of Croft's compilation of amino acid sequences of proteins is strikingly different from its predecessor, both in format and content. Disappointingly, it is no longer loose-leaf, thereby losing the useful flexibility of the first edition. It is obviously no longer possible to slip in annual supplements — a most attractive feature in a field such as protein (and nucleic acid) sequence determination that expands at such a dauntingly rapid rate. Sadly, also the useful transparent overlay to show residue numbers is no supplied, although extraordinary practice of designating N-terminal acetyl groups as residue one has been perpetuated in the second edition.

A new feature of this second edition is that approximately one-third is devoted to protein sequence determination methodology. Much of this section is admirably full of practical detail — something unfortunately often lacking in primary publications. There are some gaps however (HPLC separation of peptides is not mentioned for example), and a more extensive, separate publication would seem more satisfactory. Moreover, I suspect that a great many of those consulting a handbook of sequences are not particularly interested in the methodology.

A comparison of this handbook with Dayhoff's Atlas of Protein Sequence and Structure (Supplement 3 to Vol.5, 1978) shows that Croft's book is more up-to-date, but that it includes fewer homologous sequences from related species, no fragments and less extensive notes on the proteins.

Croft's book will be indispensable in providing the most up-to-date handbook of protein sequences currently available; but please, for the next edition, return to the loose-leaf format with annual supplements!

Linda Fothergill is a Research Officer in the Department of Biochemistry, University of Aberdeen.

IMPERIAL COLLEGE THEORETICAL SOLID STATE PHYSICS An opening exists for a

POSTDOCTORAL RESEARCH ASSISTANT

to work on the theory of spin glass under the direction of Dr D Sherrington. Tenure up to two years. Salary - £11,542 incl. London Allowance.

Applications and enquiries to Dr D Sherrington, Physics Department, London SW7 2BZ. (9076)A

NATIONAL UNIVERSITY OF LESOTHO

Applications are invited for the post of **DEMONSTRATOR IN** CHEMISTRY.

Applicants should have at least a BSc (General) with Chemistry as a major. Main duties of appointee will include demonstrating in Part I practical classes and the marking of laboratory reports and assignments for year I of the BSc. Appointment will be on contract for a two-year period initially with the possibility of renewal.

Salary scale: R 5,856 - 6,504 pa (£1 sterling = R 1.69). The University has a small number of posts within its establishment for which the British Government provides supplementation payments. The present post carries no such benefits and is offered on local terms and conditions only. Gratuity for those on shortterm contracts: inducement allowance for expatriates not qualifying for supplementation; accommodation at economic rental; family passages; baggage allowance; education allowances for expatriates; wacation and study leave.

Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent to the Registrar (Appointments), National University of Lesotho, PO Roma, Lesotho to arrive no later than August 1981. Applicants resident in UK should also send 1 copy to the Committee for International Cooperation in Higher Education, The British Council, Higher Education Division, 90/91 Tottenham Court Road, London W1P 0DT. Further details are available from either address.

(9093)A

POST DOCTORAL **POSITION**

Available immediately for cloning of photosynthetic genes in cyanobacteria. Photosynthetic mutants, transformation and cloning vectors are already available. Project will include cloning, synthesis of gene products, etc. Experience in an area of recombinant DNA technology required.

Send curriculum vitae and three letters to: Dr Lewis Sherman, Dept Biological Sciences, 110 Tucker Hall, University of Missouri, Columbia, MO. 65211. Equal opportunity (NW757)A emplover.

GRIFFITH UNIVERSITY Brisbane, Australia LECTURER -SCHOOL OF SCIENCE (Clinical Biochemistry)

The School of Science presently offers a concentration area in Biochemistry, and is planning to extend the coverage of Clinical Biochemistry to include courses at both undergraduate and postgraduate diploma levels.

It is anticipated that the main teaching duties of the present appointee will be concerned with the postgraduate courses in Clinical Biochemistry, but there will be opportunities to teach at the undergraduate level, and to pursue research interests.

Applicants for the position should oossess degrees in Chemistry, Biochemistry or Medicine and appropriate experience in the area of Clinical Biochemistry. Applications close on 31 October 1981. It is anticipated that the appointee will commence duty on 1/7/82 or as soon as possible thereafter. The appointment is budgeted for the lower portion of the salary range which is presently \$A19,821 - \$26,037.

Applicants resident in the United Kingdom and Europe may obtain further details from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WCIH OPF.

Applicants resident in North America may apply for further details from the School Adminis-trator, School of Science, Griffith University, Nathan, Queensland, 4111, Australia.

OPPORTUNITY IN CANADA

Simon Fraser University announces the formation of an institute for research on materials for the conversion and storage of energy, based on the current expertise in the Departments of Physics and Chemistry in battery electrodes and solar cells. We are reopening our search for a:

DIRECTOR OF THE **ENERGY RESEARCH INSTITUTE** and

PROFESSOR OF PHYSICS

and wish to fill this position as soon as possible. A candidate for this position will be an outstanding scientist with an established international reputation.

Applications, accompanied by a current CV and the names of three referees, should be forwarded to: Dr J C Irwin, Chairman, Department of Physics, Simon Fraser University, Burnaby, BC, Canada V5A 1S6. (604) 291-3160/3154. (NW749)A

ROTHAMSTED EXPERIMENTAL STATION Harpenden, Herts AL5 2JQ

STATISTICIAN

To work on the design and analysis of groups of experiments done by the Agricultural Development & Advisory Service of the Ministry of Agriculture, Fisheries and Food. Scope for original work; interest in computing and techniques of data handling essential.

Oualifications: Degree with statistical component. At least five years relevant post-qualifying experience is required for appointment to Higher Scientific Officer.

Appointment in the grade of Scientific Officer (£4,809 — £6,480) or Higher Scientific Officer (£6,075 £7,999) according to qualifications and experience.

Apply in writing to the Secretary naming two referees and quoting Ref 458 by 6th August 1981. Further (9087)A details on request.

City Hospital

SENIOR CYTOGENETICIST Full-time. BASIC GRADE CYTOGENETICIST

The above appointments are in the South-Trent Sub-Regional Cytogenetics Service currently housed in the Maternity Unit at the City Hospital, Nottingham, but will shortly be moving to more extensive accommodation on the same site

The successful applicants will be expected to share in all standard laboratory procedures including culturing, harvesting, slide making, staining and appropriate analysis of preparations from blood, amnistic fluid, bone marrow and other tissues. The diagnostic workload is heavy but it is hoped that, with these two new appointments all members of staff will have some time for personal work. One post is available immediately and one from 1st October, 1981

For the Senior Grade post, preference will be given to those candidates with a wide range of experience in diagnostic chromosome analysis.

For the Basic Grade post, a graduate with a reasonable degree in one of the Biological Sciences is required. Preference will be given to candidates whose degree course or postgraduate work includes a large Genetics component and/or tissue culture experience.

Further information about these posts can be obtained by ringing Dr Pat Cooke on Nottingham (0602) 608111 Extension 2785 or by visiting the Department.

Application forms are available from Personnel Services, Valebrook House, Sherwood Hospital, Hucknall Road, Nottingham. Tel: (0602) 625459 anytime.

Closing date: 30th July, 1981.

NORTH NOTTINGHAM HEALTH DISTRICT(T)

Neuropharmacologist

Greenford, Middlesex

A vacancy has arisen in our Pain Project Group in the Pharmacology Department for a neuropharmacologist to extend our investigations into the role of Substance P in pain.

The vacancy would be suitable for a pharmacology/physiology graduate who will be completing PhD studies this year, or has one or two years post-doctoral experience, in a relevant subject. Some knowledge of electro-physiological techniques would be desirable but is not essential.

The Company offers excellent conditions of employment, including a subsidised canteen, non-contributory pension scheme, bonus schemes and an active sports and social club. Generous assistance will be given with relocation where appropriate.

Please write or telephone for an application form to: Miss E. M. Butler, Personnel Department, Glaxo Group Research Limited, Greenford Road, Greenford, Middlesex UB6 0HE. Tel: 01-422 3434, ext. 2707, quoting ref. U.378.

Glaxo Group Research Ltd

(9110)A

BIOCHEMICAL PHARMACOLOGIST

Graduate — Biochemistry and/or pharmacology Experience/interest in study of neurotransmitters

We have a place for such a person to work with our pharmacologists on ligand binding studies.

Syntex Research Centre is the research division of Syntex Pharmaceuticals Limited, part of the multi-national Syntex Corporation. Our conditions of employment include a 37 hour week, bonus opportunities, Bupa and non-contributory pension, we are situated in pleasant rural conditions on a University campus on the outskirts of Edinburgh.

If you want to join our research effort please write for an application form to:

Mr A.B. Cran, Director of Personnel.

Research Park, Heriot-Watt University,

(9104)A

The University Wollongong **DEPARTMENT OF BIOLOGY** Lecturer in Ecology

(Limited term appointment of 2 years)

The appointee will be responsible for a third year course in Ecology and will be expected to contribute to other courses in the biology syllabus. Applicants should possess a higher degree and preference may be given to a candidate with post-graduate experience in Ecology. It is expected that the appointee should take up the appointment on 1st February, 1982. A tenurable lectureship in this field may be obtained from Professor A. D. Brown, Chairman, Department of Biology.

Commencing salary, according to qualifications and experience will be in the range \$A19,821 \$A26,037 per annum. Fares to Wollongong for the appointee and dependents will be paid and a relocation allowance is payable. The University will consider contributing to the cost of repatriation on conclusion of the appointment.

Applications should contain full details of qualifications, employment history, research interests, publications list, and the names and addresses of three referees and should be forwarded to the University Secretary, the University of Wollongong, Box 1144, PO Wollongong, NSW 2500, Australia. Please mark envelope 'Confidential Appointment' Applications close 1st September 1981. (9077)A

FISH PHYSIOLOGY POST DOCTORAL RESEARCH

Position available August 1, 1981 (flexible) to study corticosteroid dynamics and physiology in adult Atlantic salmon

Salary \$14,000. Second year possible. PhD with experience in radioimmuno assays preferred.

During the Canadian postal strike send curriculum vitae and two letters of reference to

NATURE Box NW753 15 East 26th Street Suite 1503 New York, NY 10010

Otherwise applications should be sent to: Dr Melvin Wiesbart, Dept of Biology, St Francis, Xavier University, Antigonish, Nova Scotia, Canada B2G 1C0 (NW753)A

KING'S COLLEGE **HOSPITAL** RESEARCH ASSISTANT/

New graduate with Honours degree in Biochemistry or Chemistry required to work on the development of immunoassays for use in reproductive medicine.

BIOCHEMIST

Starting salary: £5,873 pa (under review).

For job description and application forms contact District Personne Department, King's College Hospital Department, King S College Prospital Denmark Hill, London SE5 9RS Telephone: 01-737 0348 (24 hours Ansaphone) quoting reference no DP/202. Informal enquiries may be made by contacting Professor Colins on 01-274 6222 Ext. 2568.

Post tenable to 31st March 1982 in the first instance, and subject to annual renewal. (9097)A

RESEARCH AND DEVELOPMENT PERSONNEI **NUCLEAR WASTE MANAGEMENT** Systems Waste Geotechnical Engineering Chemistry Development **Assessment Immobilization** Research

Challenging opportunities exist at the Whiteshell Nuclear Research Establishment for individuals to participate in an expanded research and development program for the immobilization and disposal of nuclear wastes.

The program offers a unique opportunity to participate in team-oriented R&D with wide scope for initiative, responsibility and collaboration with other scientific groups in Canada and abroad.

We require interested and/or trained personnel for the areas of:

SYSTEMS ASSESSMENT:

numerical analysis, hydrogeological modelling and risk

assessment

WASTE IMMOBILIZATION: GEOTECHNICAL RESEARCH: CHEMISTRY:

materials science, metal corrosion, glass and ceramics geology, hydrogeology and geomechanics

geochemistry. hydrogeochemistry, chemistry actinides, chemical processing and applied chemistry

ENGINEERING DEVELOPMENT: chemical, mechanical, geotechnical, instrumentation

and civil

The Whiteshell Nuclear Research Establishment is located in a wooded area on the banks of the Winnipeg River 105 km northeast of Winnipeg and employs approximately 900 people. It has modern laboratories and equipment, is organized as a multi-discipline research centre and undertakes a wide range of scientific and engineering activities.

Starting salaries are commensurate with qualifications and experience. We have a comprehensive benefits package and relocation assistance is provided.

Men and women who may be interested in these positions and possess the necessary qualifications should apply in writing giving full particulars to: Personnel Supervisor, Atomic Energy of Canada Limited — L'Energie Atomique du Canada, Limitee WHITE-SHELL RESEARCH ESTABLISHMENT, PINAWA, Manitoba, R0E 1L0; or you may call (204) 753-2311. Please indicate your area of interest on your letter of application.

Atomic Energy Research Company

L'Énergie Atomique of Canada Limited du Canada, Limitée Société de Recherche

Senior Behavioural Pharmacologist

Eli Lilly & Company is one of the world's largest producers of ethical pharmaceutical, animal health and agrochemical products. At our U.K. Research Centre, situated near Camberley in Surrey, we are actively engaged in basic research and development on a variety of projects.

A vacancy has arisen for a SENIOR BEHAVIOURAL PHARMACOLOGIST to lead a small section of three people within a multi-disciplinary C.N.S. group.

This group has a commitment to basic research and our laboratories are well equipped with on-line computer control and testing equipment.

This challenging appointment would ideally be suited to a Ph.D. candidate with 2-3 years' experience in research.

The compensation package includes a competitive salary, noncontributory pension and life assurance schemes, B.U.P.A. membership, 21 days' holiday and flexible working hours. Assistance with relocation costs will also be considered, where appropriate.

Please write to Sue Smith, Personnel Manager.

(9113)A

LILLY RESEARCH CENTRE LTD.

ERLWOOD MANOR, WINDLESHAM SURREY, TEL: (0276) 73631.

Midland Centre for Neurosurgery and Neurology

Basic/Senior Biochemist

Applications are invited from graduates in Biochemistry and related sciences for the above full time vacancy in the Clinical Chemistry Section of the Pathology Department at the above hospital.

A wide range of routine and special investigations is carried out, and participation in research will be encouraged.

User experience with one or more of the following analytical methods would be an advantage, although not essential: G.L.C., H.P.L.C., I.R., Spectroscopy, Radio isotope assay, isotachophoretic analysis.

Whitely Council conditions of service and salary applicable to this post. The Midland Centre for Neurosurgery and Neurology (81 beds) is a regional centre for the treatment of neurological and neurosurgicl diseases, situated approximately 4½ miles north-west of Birmingham. An excellent motorway network provides quick and easy access to many surrounding rural and residential areas.

Interested applicants may visit the department by appointment — telephone Mr R.A. Westhead, Principal Biochemist, on 021-558 3232

Applications in writing, stating age, qualifications, previous experience, together with the names and addresses of two referees to the Hospital Secretary, Midland Centre for Neurosurgery and Neurology, Holly Lane, Smethwick, Warley, West Midlands.

Closing date for receipt of applications: 31st July 1981.(9064)A

THE UNIVERSITY OF SHEFFIELD DEPARTMENT OF GENETICS

Applications are invited from men and women for the post of Research Assistant in the above department, funded by the Science Research Council, to work on a project on mitotic errors in Aspergillus nidulans. Experience in fungal genetics desirable but not essential. Tenable for three years from a date to be arranged. Initial salary up to £6,880 a year.

Details from Professor J. A. Roper, the Department of Genetics, the University, Sheffield S10 2TN to whom applications, with the names of two referees, should be sent by 14 August 1981. Quote ref. R609/G. (9081)A

THE UNIVERSITY OF MANCHESTER DEPARTMENT OF BIOCHEMISTRY

RESEARCH ASSISTANT IN BIOCHEMISTRY

Applications are invited for this postdoctoral post to work on the reconstruction of the insulin receptor and glucose transporter in bilayer systems. Salary on Range IA starting at £6,880 pa.

Applications with curriculum vitae and names of two referees to Dr M N Jones, Department of Biochemistry, The University, Manchester M13 9PL. (9058)A

OTAGO Dunedin, New Zealand IPORARY LECTURER I

TEMPORARY LECTURER IN CLINICAL/MEDICAL MICROBIOLOGY

UNIVERSITY OF

Applications are invited from science graduates for a temporary post as Lecturer in Clinical/Medical Microbiology. This is a one-year appointment which could be extended to 18 months.

The appointee will be expected to: (1) Act as a consultant in medical microbiology to the Otago Hospital Board. It is anticipated that this consultation should occupy about 50% of the time; (2) Contribute to the teaching of the University Department of Microbiology and to join in on-going research project or undertake independent research.

Salary: NZ\$19,140 — \$23,520 per annum, depending upon qualifications and experience. A particularly well suited and qualified applicant could be appoined at the level of Senior Lecturer.

A portion of the salary may be paid as a direct grant for fares and travel expenses of the appointee and his or her family. The residue will be subject to new Zealand income tax.

Further particulars are available from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University, PO Box 56, Dunedin, New Zealand.

Applications close on 31 August (9085)A

POST-DOCTORAL RESEARCH ASSOCIATES

Positions are available immediately for recent graduates in cell biology and biochemistry to work in the areas of intracellular binding and internalization of gonadotropins.

The candidates should have experience in processing tissues and isolated subcellular organelles for EM examination, their morphological assessment, autoradiography — electron microscopy or biochemical techniques related to the above project.

Qualified candidates contact: Dr Ch V Rao, Dept of OB/GYN, 436B MDR Bldg, University of Louisville, Louisville, Ky 40292. (NW752)A

POSTDOCTORAL ASSOCIATE. Position available September 1981 or after. Postdoctoral Associate to work on rapid kinetics or hemoglobin and the study of protein conformation. Salary commensurate with experience. Send résumé to: Dr Quentin H Gibson, Section of Biochemistry, Molecular and Cell Biology, Wing Hall, Cornell University, Ithaca, New York 14853. An Equal Opportunity/Affirmative Action Employer. (NW754)A

RESEARCH ASSOCIATE

Position available immediately for PhD to work on biochemical and physiological mechanisms in the crystalline lens in relation to cataract development. Experience in membrane or protein biochemistry would be most advantageous. Send curriculum vitae to University of Colorado Health Sciences Center, 4200 E 9th Ave, Denver, Colorado 80262, USA. The University of Colorado is an equal opportunity employer. (NW750)A

UNIVERSITY OF DUNDEE Department of Biochemistry POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited for a Post-Doctoral Research Assistant to work on an SRC supported project investigating the structure of hydrogenase from E coli. The project involves protein chemical characterisation of the isolated and membrane bound enzyme and the cloning of its structural gene. Experience in membrane protein characterisation and/or recombinant DNA technology would be advantageous. The appointment is available from 1 October 1981 or as soon as possible thereafter and will be for a period of up to three years. Applications, accompanied by a curriculum vitae and the names of two referees should be submitted by August 6th 1981 to K. M. Cocker, Assistant Personnel Officer, The University, Dundee DD1 4HN, from whom further particulars are available. Please quote ref. EST/44/81J. (9099)A

Assistant Professor

Applicants are invited for a tenure track position at the rank of Assistant Professor. Candidates possessing an M.D. or Ph.D. several years of postdoctoral experience, and a strong commit-ment to developing an independent research program are sought. Applicants with research interests in neuropharmacology, toxicology, or molecular biology are preferred, but applications from outstanding candidates in any area of pharmacology are welcomed. Responsibilities include participation in departmental responsibilities for medical and graduate student training.

Inquiries, which should include a curriculum vitae, synopsis of current research interests, list of publications, reprints of selected publications, and the names of three references should be addressed to: Professor Cheng-Wen Wu, Chairman, Faculty Search Committee, Department of Pharmacological Sciences, School of Medicine, Health Sciences Center, SUNY Stony Brook, Stony Brook, NY 11794.

SUNY Stony Brook is an equal opportunity/affirmative action employer. AK#92A. (NW746)A

Instrumentation Specialist

University of Petroleum & Minerals Dhahran, Saudi Arabia

The University of Petroleum & Minerals, Dhahran, Saudi Arabia, is seeking for its chemistry department a full-time specialist to service the department's major instrumentation-Varian XL 200 ft NMR superconducting spectrometer, ENRAF Nonius CAD-4 automatic diffractometer, RIBERMAG GC-MS and emission spectrograph. New acquisitions will include EPR and ENDOR spectrometers.

Applicants should have a least a B.S. in electronics, or a B.S. degree in chemistry, physics or chemical engineering with training in electronics, and be knowledgeable in the operation and maintenance of computer-interfaced instrumentation. Experience with magnetic resonance is preferred. Responsibilities will include the maintenance, troubleshooting and repair of these instruments.

Minimum regular contract for two years, renewable. Competitive salaries and

allowances. Air-conditioned and furnished housing provided. Free air transportation to and from Dhahran each year. Attractive educational assistance grants for schoolage dependant children. All earned income without Saudi taxes. 10½ months duty each year with 45 days vacation with salary plus other fringe benefits as per policy.

Apply with complete résumé on academic, professional and personal data, together with photograph, list of references, copies of certificates, diplomas and degrees and home and office addresses and telephone numbers to:

Dean of Faculty and Personnel Affairs, University of Petroleum & Minerals, P.O. Box 144, Dhahran International Airport.

Dhahran International Airport Dhahran, Saudi Arabia.

Hoechst &

is planning to extend considerably its gene technology group in Frankfurt (Main), Germany involved in basic research with special regard to health care.

We are inviting applicants for

Molecular Biology

with several years experience in recombinant DNA research and nucleic acid biochemistry.

Salary will be competitive and in accordance with experience. Applicants should have basic knowledge in German language. Applications, including curriculum vitae (with a description of previous experience) should be sent to:

Hoechst Aktiengesellschaft, Personalabteilung T, Referat Naturwissenshaftler, Postfach 80 03 20. 6230 Frankfurt (Main) 80

(W380)A

SYNCHROTRON RADIATION RESEARCH MRC/SERC JOINT APPOINTMENT

The Medical Research Council and the Science and Engineering Research Council have agreed jointly to appoint a Post Doctoral Research Associate to work at the SERC Synchrotron Radiation Source (SRS) at the Daresbury Laboratory. This appointment provides a unique opportunity for the right man or woman to make an original contribution to an expanding field of research. The successful applicant would be expected to take responsibility for supporting the exploitation of the SRS in the field of biological and medical applications of small angle x-ray scattering and to participate in the research programme. Projects already approved include work on proteins, muscle and viruses, and the appointee would be expected to act as a focal point for these activities and to advise and assist other SR users in this area. An experimental station is being commissioned and will be available for some of this work but the appointee would be expected to take part in the design, construction and operation of further equipment. For this reason, the appointee should have a good understanding not only of the application of SR to biological problems but also of electronic methods of x-ray detection and data collection. The ability to work as a member of a team and to have an enthusiasm for the development of new techniques are essential qualities.

An appointment will be made at a salary between £5862 and £9015 per annum fixed according to age, qualifications and experience. The post will be available for a fixed term of three years and will be superannuable.

Closing date: 31st August 1981.

For further information please write to or telephone Warrington (0925) 65000 Dr. P. J. Duke (Ext. 460). Applications should be sent together with curriculum vitae and the names and addresses of two referees, quoting reference number DL/765/

RESEARCH ASSISTANT

The Environmental Epidemiology Unit of the Medical Research Council based at Southampton General Hospital has a vacancy for a Research Assistant. This is a new Unit whose main interest is determining environmental causes of disease in

The successful applicant will assist the Director with surveys mainly in the field of cancer. The work may include interviewing patients and travelling within England. A numerate graduate with at least one year's experience in survey work or an appropriate MSc will be preferred.

The appointment will be in the Research Assistant Grade 1B, for a period of three years and salary will be in the range £5,285 — £7,700, depending on age, qualifications and experience. The post will be superannuable under the Universities Superannuation Scheme.

Further particulars and application forms from the Secretary to Professor E D Acheson, MRC Unit in Environmental Epidemiology, South Lab/Path Block, Level F, Southampton General Hospital, Southampton. (Tel: Southampton 777222 Ext. 3984.) Closing date for applications August 14th. (9098)A

LOTHIAN HEALTH BOARD

METABOLIC UNIT

Western General Hospital, Edinburgh

Applications are invited for the appointment of a:

SENIOR GRADE BIOCHEMIST

in the above Unit which is concerned with the management of, and research into endocrine, metabolic and nutritional disorders. Previous relevant experience required. Suitable candidates may register for a higher degree and may take part in the MCB training programme run by the Departments of Clinical Chemistry. Salary on the scale £7,674—£9,921. Whitely Council conditions of service apply.

Further particulars may be obtained by contacting the Secretary, Metabolic Unit, Western General Hospital, Crewe Road, Edinburgh EH4 2XU, Telephone 031-332 2525, extension 365.

Applications, which should be typewritten, giving particulars of age, qualifications and previous experience, together with the names, addresses and telephone numbers of two referees should be lodged with the Secretary, 11 Drumsheugh Gardens, Edinburgh as soon as possible, but not later than two weeks from the date of this advertisement. (9063)A

GUY'S HOSPITAL Basic Grade Physicist

Required to join the Department of Clinical Physics and Bioengineering. The person appointed will work primarily in non-ionising radiation aspects of Medical Physics inlcuding clinical instrumentation and physiological measurement. Applicants should have a good degree in physics or electronic engineering. Salary in the range of £5,873 to £7,637 (inclusive), depending on qualifications and experience.

Gratorex, Dept. of Clinical Physics and Bioengineering. Application forms from the Personnel Officer, Guy's Hospital, St Thomas Street, London SE1. Tel: 01-407 7600 Ext. 3471 quoting reference P/30. (9070)A

GENETIC resources conservation. A vacancy exists at the International Institute of Tropical Agriculture, Ibadan, Nigeria, for a scientist to co-ordinate the activities of the Institute's Genetic Resources Unit. The successful applicant must have a doctorate in the field of crop science, botany, or genetics and previous experience of crop breeding and/or genetic resources conservation. As well as the collection, maintenance, evaluation, documentation and preservation of large amounts of food legume and rice germplasm, the Unit Co-ordinator and his staff work closely with the Institute's and other crop improvement programs to promote the use of germplasm. The Unit runs an annual training course for African Technicians in many aspects of crop genetic resources conservation. Applications direct to: Director for Administration, International Institute of Agriculture, Oyo Road, PMB 5320, Ibadan, Nigeria. (9068)A

Commissioning Editor

Academic Press seeks a new Commissioning Editor with publishing experience and preferably with a background in or experience of physics, earth sciences, materials sciences or engineering.

Please write with full career information to:

Anthony Watkinson, Academic Press Inc. (London) Ltd., 24-28 Oval Road, London NW1 7DX (9112)A

KING'S COLLEGE London DEPARTMENT OF BIOPHYSICS POSTDOCTORAL

POSTDOCTORAL RESEARCH ASSISTANTS

- 1) Biochemist with experience in nucleic acid and protein chemistry or enzymology to study the mechanism of chromatin transcription in vitro. Post tenable for 2 years from 1 September 1981. Salary in the range £6,070 to £8,515 plus £967 London allowance. USS.
- 2) Cell Biologist or Biochemist with experience in tissue culture and recombinant DNA techniques to study the structure and expression of cloned genes in eukaryotic cells. Post tenable for 2 years from 1 September 1981. Salary in the range £6,070 to £9,335 plus £967 London allowance, USS.

Please reply as soon as possible, with a curriculum vitae and the names and addresses of two referees, to Dr H J Gould, Department of Biophysics, King's College, 26-29 Drury Lane, London WC2B 5RL. (9051)A

THE ROYAL VETERINARY COLLEGE University of London

DEPARTMENT OF MICROBIOLOGY AND PARASITOLOGY POSTDOCTORAL VIROLOGIST/ IMMUNOLOGIST

A postdoctoral worker is required to assist in investigations of the pathogenesis of a herpesvirus-induced paresis in horses. The two-year, grant-aided project offers a salary in the range of £6,299 — £8,095, plus £967 London Allowance per annum. Entry point would be according to experience and qualifications. Further information about the work can be obtained from Dr N Edington.

Application form and further letails obtainable from Assistant Secretary (Personnel), The Royal Veterinary College, Royal College Street, London NW1 0TU (Tel: 01-187 2898 Ext. 264). (9074)A

WASHINGTON STATE UNIVERSITY

FACULTY FOR INSTITUTE OF BIOLOGICAL CHEMISTRY

An outstanding scientist is being sought to fill a permanent faculty position in the Institute. This person will be expected to conduct a vigorous research program in biological chemistry relevant to agriculture and participate in graduate teaching. Salary and rank are open to negotiation. Review begins September 1, 1981.

Send nominations and applications, including a curriculum vitae, a short description of research goals and a list of three or more references to P E Kolattukudy, Director, Institute of Biological Chemistry, Washington State University, Pullman, Washington 99164.

Washington State University is an equal opportunity/affirmative action employer. (NW735)A

OREGON STATE UNIVERSITY

SCHOOL OF OCEANOGRAPHY IGNEOUS/METAMORPHIC PETROLOGIST

Faculty position, 12-month, tenuretrack. Candidate expected to develop strong research program emphasizing the application of latest theoretical, experimental and geochemical methods to petrological problems, particularly those related to the formation of oceanic crust, islands, and/or volcanic arcs.

Rank is Assistant/Associate Professor. Salary: \$23,000-\$38,000 commensurate with experience.

Send résumé and names of three references by 1 September 1981 to: G Ross Heath, Dean, School of Oceanography, Oregon State University, Corvallis, Oregon 97331.

OSU is an Affirmative Action/ Equal Opportunity Employer. (NW755)A

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

(University of London)

Keppel Street/Gower Street, London WC1E 7HT

POSTDOCTORAL RESEARCH FELLOWS

Applications are invited for two posts in the Department of Medical Protooology for biochemical parasitologists to investigate: 1) Metabolism in nalaria parasites; 2) The mode of action of antiprotozoal drugs. Candidates hould have a strong background in biochemistry and experience in cultivation echniques, preferably with parasitic protozoa.

The posts are initially for one year, commencing October 1981 or earlier, 71th a possibility of renewal. Initial salary not less than £7,037 gross depending 10 qualifications and experience.

Applications, with *curriculum vitae* and the names and addresses of two eferees, should be sent as soon as possible to The Senior Assistant Secretary at 1e School. (9062)A

National Research Council Canada Conseil national de recherches Canada

RESEARCH OFFICER

The Canada Centre for Space Science of the National Research Council of Canada requires a Research Officer. As a Space Scientist in the Scientific Planning and Evaluation Group, the duties will include:

- Assisting in the evaluation and processing of proposals received by the CCSS for the rocket and balloon program, the satellite program and supporting ground-based experiments.
- Participating in the planning of scientific campaigns forming part of the above programs and in scientific working groups associated with the experiments.
- Perform studies pertaining to monitoring and evaluating the functioning of the above programs as and when required.
- Participating in CCSS national and international committees and working groups as required.
- Participating as an investigator (experimental or theoretical) in CCSS associated scientific programs.
- Performing other associated duties as required.

Preference will be given to candidates having a PhD in Physics with several years' experience in space science or equivalent research experience in space science.

Salary — Up to \$30,430 per annum depending on qualifications.

Apply in writing to the Employment Officer, National Research Council of Canada, Ottawa, Ontario, K1A 0R6. In reply, please quote CCSS-81-2-N.

(NW747)A

Canadä

UNIVERSITY OF ZÜRICH (Switzerland) FACULTY OF VETERINARY MEDICINE

invites applications for the position of

PROFESSOR in VETERINARY PHYSIOLOGY

Applicants should have a higher degree, a PhD or an equivalent qualification in veterinary physiology and teaching experience at university level. They are expected to perform and to direct experimental research, to teach physiology (in German) to undergraduate veterinary students and to be head of the institute of veterinary physiology.

Salary range: SFr. 99 300 to 128 200 (1SF_E = 0.5 US\$).

Applications including a curriculum vitae and a list of the applicant's published papers should be addressed to the Dekanat der Veterinärmedizinischen Fakultät der Universität Zürich, Winterthurerstr. 260, CH 8057 Zürich (Switzerland) to arrive no later than October 1, 1981.

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified persons for appointment to the following positions:

RESEARCH SCHOOL OF BIOLOGICAL SCIENCES DEPARTMENT OF DEVELOPMENTAL BIOLOGY RESEARCH FELLOW

The successful applicant will be expected to undertake research on the developmental biology of plants. The Department has special interests in plant hormones, tissue culture, and cell biology. Applications in all these areas will be considered but preference will be given for work on aspects of development utilising ultrastructural and/or immunological approaches. Applications should include a summary of research interests and proposals, together with the names and addresses of three referees.

Closing date: 11 September 1981.

DEPARTMENT OF POPULATION BIOLOGY RESEARCH FELLOW

The successful applicant will work in the fields of developmental molecular biology or genome structure. Current research is concerned with developmental aspects of the genome of *Drosophila* using cloning, sequencing and genetic techniques. The applicant would be expected to contribute to studies analysing developmental mutants or developmental facets of genome structure in *Drosophila* or mammals. The position will not be available until June 1982.

Closing date: 11 September 1981.

FACULTY OF SCIENCE DEPARTMENT OF PHYSICS LECTURER

The successful applicant will hold a PhD and should be prepared to teach undergraduate courses at all levels and will be required to participate in experimental research in the department using pulsed and c.w. dye lasers to study the interactions of their radiation with atomic systems. A person with a good theoretical background in quantum mechanics of such interactions would be preferred.

The appointee should be able to take up duty without delay.

Closing date: 30 September 1981.

Salary will be in accordance with qualifications and experience within the ranges: Lecturer \$A19,821 — \$A26,037 p.a.; Research Fellow \$A19,821 — \$A25,871 p.a. Current exchange rages are \$A = \$US1.14 = £Stg.0.57p.

Unless otherwise stated, appointment as Research Fellow will be for up to three years with possibility of extension to five years. Lecturer: four years in the first instance, with possibility, after review, of reappointment to retiring

Reasonable travel expenses are paid and assistance with housing is given for an appointee from outside Canberra. Superannuation benefits are available for applicants eligible to contribute. The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should obtain further particulars from the Registrar, P.O. Box 4, Canberra ACT 2600, Australia, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, before submitting applications

(9100)A

SHEFFIELD AREA HEALTH AUTHORITY (TEACHING)

CENTRE FOR HUMAN GENETICS

CYTOGENETICIST

There is a vacancy for a Cytogeneticist (Basic Grade) at the above Unit. The work is part of a Regional diagnostic service and will include tissue culture and the identification of chromosome abnormalities.

Applicants should have a relevant Science degree.

Salary Scale £5,346 per annum rising to a maximum of £7,110 per

Applicants wishing to visit the Laboratory or requiring further information should telephone Mr A.M. Potter at Sheffield (0742) 667333.

Applications, together with curriculum vitae and the names and addresses of two referees, should be sent to the District Personnel Officer, B Floor, Royal Hallamshire Hospital, Glossop Road, Sheffield S10 2JF.

Closing date for applications: 24th July 1981.

(9067) A

UNIVERSITY OF WARWICK

POSTDOCTORAL FELLOW IN

BIOLOGICAL SCIENCES

This post in the Chloroplast Research Group is part of a SERC grant for the study of the role of light in controlling chloroplast development in higher plants, with specific reference to the involvement of phytochrome in the expression of nuclear genes encoding chloroplast proteins. Experience with phytochrome, radioimmunoassay or nucleic acid hybridization would be an advantage.

The post is tenable from 1st October 1981 on the Research Range IA scale: £6,070 to £10,575 pa.

Applications (no forms) should include a curriculum vitae, and the names of two referees to the Academic Registrar, University of Warwick, Coventry CV4 7AL and quote Ref No 48/A/81/0. Informal enquiries to Dr J Bennett, Department of Biological Sciences by 7th August, 1981. (9102)A

THE UNIVERSITY OF MANCHESTER FOETAL EPITHELIAL **PHYSIOLOGY**

Applications are invited for the post of

TEMPORARY LECTURER

held jointly between the Departments of Physiology and Child Health. Research will be on ion transfer across the placenta mainly in sheep or pigs. Teaching duties will be in the Department of Physiology. This is a new venture and the initial appointment will be for a term of three years. The possibility exists for the appointment to be made substantive if the joint appointment is a success. Initial salary range pa: £6,070 — £7,290.

Particulars and application forms (returnable by September 1st) from the Registrar, The University, Manchester M13 9PL. Quote ref. (9004)A 127/81/N.

WELSH NATIONAL SCHOOL OF MEDICINE (University of Wales) DEPARTMENT OF MEDICAL BIOCHEMISTRY

POST-DOCTORAL RESEARCH OFFICER

Applications are invited for the above 2-year appointment to work with Dr A K Campbell and Dr G R A Hunt on the application of nuclear magnetic resonance spectroscopy to the study of cell injury. Starting salary up to £6,070 on the scales for University Research and Analogous staff.

Candidates should have completed the work for a PhD in chemistry, biochemistry or a related discipline. Previous experience of NMR is an advantage, but not essential.

Further particulars (quoting reference No C38/4/37) from the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff CF4 4XN (tel no 0222/755944 ext 2296). Closing date for application 25th July, 1981 (9089)A

UNIVERSITY OF LIVERPOOL DEPARTMENTS OF

GENETICS AND BOTANY **TECHNICIAN** (GRADE 3)

to work on the genetic analysis of the bacterium Streptomyces. Candidates should have experience in microbiology, genetics or biochemistry, and an interest in microbial genetics.

Minimum qualifications ONC plus three years experience, but suitable for recent graduate.

Salary within range £4,672 -£5,473 pa.

Application forms can be obtained from the Registrar, The University PO Box 147, Liverpool L69 3BX Quote Ref. RV/850/N. (9080)A

STUDENTSHIPS

The Hatfield Polytechnic School of **Natural Sciences RESEARCH IN** GEOLOGY, CHEMISTRY, **CROP PROTECTION**

Applications are invited from appropriately qualified graduates for the following posts:

SRC CASE Studentship

Investigations of road-making materials in South-West England.

SRC CASE Studentship

Chemistry of cement forming compounds.

Postdoctoral Fellowship Research Assistantship

Both into novel methods of meta recovery from complex ores.

Research Studentship

Crop Protection.

Application forms and further details from the Staffing Office. The Hatfield Polytechnic, PO Box 109, College Lane, Hatfield, Herts (Hatfield 68100, ext. 309).

UNIVERSITY OF ABERDEEN DEPARTMENT OF CHEMISTRY

SRC CASE STUDENTSHIP Molecular Sieve Precursors

A three year grant, in association with Unilever Research, is availab for research into the mechanism formation of zeolite molecul-sieves. The holder will form part an active group working in the are and will gain experience of a varie of techniques.

The grant, which is subject to the usual SRC requirements (Briti nationality, first or upper secon class honours degree), carries a sm supplement above the usual SF

For further details, contact Dr I Dent Glasser, Department Chemistry, University of Aberdee Meston Walk, Old Aberdeen A 2UE, as soon as possible. (9090)F

THE OPEN UNIVERSITY

SRC Research **Studentships**

A SRC studentship is available from 1st October, 1981 for a student to undertake biological/biophysical research on regular tissues (muscle, cornea, possibly lens) using biochemical and electro-physiological methods, and light and X-ray diffraction, including high intensity synchrotron X-ray diffraction and neutron diffraction.

The work would be with the Biophysics Research Group (Chairman, Professor G. F. Elliott) of the Oxford Research Unit. Our laboratory is well equipped and based in a pleasant country mansion with wooded grounds on the outskirts of Oxford.

We are looking for a graduate with a first (or upper second) class degree in biological sciences, chemistry/biochemistry or in physics with some biological interests.

Please contact Professor Elliott, Dr Zehra Sayers or Dr Else Bartels by letter or telephone. (OXFRU, Foxcombe Hall, Boars Hill, Oxford; 0865 730731). Please quote Please quote reference (SO/3). (9084)F

THE UNIVERSITY **OF SHEFFIELD DEPARTMENT OF HUMAN METABOLISM AND CLINICAL BIOCHEMISTRY**

Applications are invited for a Postgraduate Research Studentship tenable from 1 October 1981. The successful applicant would work in one of the following areas: 1) Intracellular control mechanisms of pituitary hormone secretion; Neuroendocrine control in the hypothalmic-pituitary hormone secretion; 3) Mechanisms of inflammation and control of proteinase and prostaglandin production by human chondrocytes in relation to arthritis; 4). Vitamin D metabolism in man in health and disease; 5) Biochemical control of human blood platelet function. The Department has excellent facilities for laboratory and clinical work, with emphasis on endocrinology, connective tissue biology, cancer research and throm-bosis. Other topics are available.

Applications, including curriculum vitae and the names of two referees, should be sent to Professor R. G. G. Russell, Department of Human Metabolism and Clinical Biochemistry, University of Sheffield Medical School, Beech Hill Road, Sheffield S10 2RX (tel: 0742 26484, Ext. 3037) as soon as possible. UNIVERSITY OF WARWICK

Compton Scattering Studies of Electron Density

A SRC supported two year

POSTDOCTORAL FELLOWSHIP is available in the Department of Physics, for gamma-ray Compton scattering studies of charge density in transition metals and their alloys. Most of the experiments will be carried out using the recently commissioned ²⁴¹Am Compton spectrometer at Warwick, but some of the experiments are scheduled for the high energy Compton spectrometer at the Rutherford SRC Laboratory. The successful applicant will play a major role in the planning, execution and computational analysis of the experiments, working with a graduate research assistant under the direction of Dr M J Cooper.

The appointment, to commence on or before 1st October 1981, will be made at the second or third point of the Research Range IA scale: (currently £6,475 — £6,880 pa respectively).

Informal enquiries to Dr Cooper, Department of Physics; application Department of Frigores, approached forms from the Academic Registrar, University of Warwick, Coventry CV4 7AL quoting Ref. No. 47/A/81/0. Closing date for receipt of applications 7th August, 1981.

(9061)E

UNIVERSITY OF WARWICK

RESEARCH FELOWSHIP

IN

VIROLOGY/BIOCHEMISTRY/ **IMMUNOLOGY**

Our recent work suggests that antigenic modulation is responsible for the neutralization of influenza virus by antibody, since monoclonal anti-haemagglutinin antibody inhibits the activity of the internal virion transcriptase.

We are seeking applicants with a background in biochemistry/virology/ immunology to study the molecular aspects underlying this phenomenon, assisted by a research technician and as part of a large group working on related topics under the direction of Dr N J Dimmock.

The post is funded by the Medical Research Council for three years, on the Research Range IA scale: £6,070 to £10,575 pa. Informal enquiries to Dr N J Dimmock, Department of Biological Sciences.

Applications (no forms) giving details of age, qualifications and experience together with the names of two referees to the Academic Registrar, University of Warwick, Coventry CV4 7AL quoting Ref No: 48/2A/81/0 by 7th August, 1981. (9103)E

AGRICULTURAL RESEARCH COUNCIL

INSTITUTE OF ANIMAL PHYSIOLOGY Babraham, Cambridge CB2 4AT

POST DOCTORAL RESEARCH FELLOWSHIP

Applications are invited for a post doctoral appointment financed for a period of up to 3 years by the National Research Development Corporation in one of the following fields:
i) Chemical carcinogemesis and cell transformation in vitro;

ii) Hybridoma production. Both areas will involve study of animal and/or human cells secreting hormones or antibodies.

Candidates should have a 1st or upper 2nd class honours degree and at least 2 years post-graduate experience in molecular biology and/or immunology and aquaintance with cell culture techniques.

Salary in Higher Scientific Officer scale (under review) £6,075 to £7,999 Starting pay according to experience non contributory pension scheme.

This post can be discussed in more detail with Dr W Mason on Cambridge (0223) 832312. Application forms from the Secretary of the Institute quoting reference NRDC1. Closing date: (9106)E 31.7.81.

EMBO

European Molecular Biology Organisation LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY SPRING 1981 AWARDS

Next deadline: August 15, 1981

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country. Long term fellowships are awarded initially for one year, but subject to review of progress by the selection committee, they are usually renewed for a second year. In cases of exceptional scientific merit renewal for a third year is possible. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is August 15, 1981. Successful candidates will be notifed of their awards immediately after the meeting of the selection committee which is on October 23, 1981.

Application forms and further details may be obtained from Dr. J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F.R. Germany.

Please mention

nature

when replying to these advertisements

Definitive, Complete, Authoritative

NATURE announces the publication in 1981 of the Annual Directory of Biologicals and Disposable Chemicals. The directory will be available for distribution to all NATURE subscribers in the Autumn of 1981. It will also be marketed separately, offering an even larger distribution.

A New Buyers guide

The basic thrust of the directory will be to provide NATURE subscribers with a definitive reference catalogue from which they may purchase the chemicals and disposables listed.

From research conducted around the world the NATURE marketing staff has determined the need for a directory of biologicals, disposable chemicals and gases. Probably more than any other scientist, the NATURE reader represents the largest potential market for the sale of these chemicals.

Every attempt will be

made to produce a catalogue that will reference the worldwide market of chemical manufacturers, distributors, suppliers, and exporters.

No instrumentation or apparatus listings will be included in this directory; its sole purpose is to provide detailed information for our readers as to where they may secure the biologicals, chemicals and gases for use in their

laboratories.
The directory will be cross-referenced and include chemical classifications, product classifications, geographical location of suppliers and other referenced information as needed.

NATURE Directory of Biologicals

What's in It?

The directory will include (but not be limited to) these biological reseach chemicals

- immunochemicals
 - cell lines
 - fine chemicals
 - reagents
 - enzymes
 - isotopes
 - monoclonals
 - gases, etc.

Companies write for details NOW!

I'm interested in knowing more about Nature's new Directory of Biologicals.

We not only made the world's first radioimmuno assay liquid scintillation counter. We made it self-calculating too!

The Philips RIA LSC is the only liquid scintillation counter in the world completely dedicated to radioimmuno assay. It's also the only one which can perform the full range of RIA calculations, giving a direct print-out of the result, e.g. hormone concentration value.

Furthermore, its built-in microcomputer can also store up to 15 different measuring programmes, each with a wide range of parameter settings.

But, despite this capability, operation is simple, convenient and efficient. Programme/parameter set-up is via a user-orientated keyboard. The programme to be used is then selected by punching holes in the programme selection card fixed to the tray. This gives positive sample identification and permits multi-user operation that so means that sample trays can easily be re-arranged after loading without disrupting the programming, thereby catering for urgent jobs.

With its sample capacity of 310 (31 trays of 10 standard or mini vials each), the Philips RIA LSC can carry out up to 15 different RIA tests without supervision – just producing rapid, accurate results.

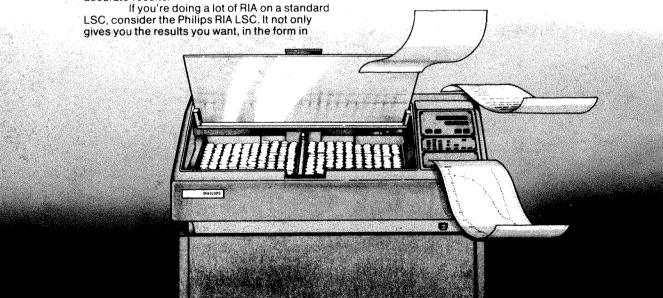

which you want them, but because it is dedicated to RIA and does not require an external computer for calculations, it also works out considerably cheaper.

And if you are already one of the many Philips LSC users, with a few interchangeable accessories you can have the best of both worlds.

Calculation possibilities include: – automatic calculation and plotting of weighted dose response curve(s) for single and dual labelled samples; curve optimisation in area of interest; comparison between entered and calculated concentrations; replicate averaging with % coefficient of variation; automatic elimination of faulty standards; calculation of actual concentrations of unknown samples; etc.

Programme parameters include: – window settings; background subtract; normalisation count; number of replicates; pre-set time; pre-set count; repeat count; low count reject; bound or free fraction; output format (e.g. CPM, DPM, % Bound, or Concentration).

MAJOR NEW SERIES

TOPICS IN MOLECULAR & STRUCTURAL BIOLOGY

General Editors:

WATSON FULLER.

Department of Physics, University of Keele.

STEPHEN NEIDLE.

Department of Biophysics, King's College, London.

TOPICS IN MOLECULAR AND STRUCTURAL BIOLOGY is a major new series which is aimed at emphasising interest in three-dimensional structure – the feature which most obviously characterises molecular biology as a discipline.

Each volume will focus on a particular family of biological macromolecules or a well-defined area of structural interest. The contributions will be chosen to reflect the wide range of physical and chemical techniques which characterise contemporary approaches to problems in molecular biology.

The aim will be to highlight topics of high current interest rather than to provide a text with uniform and comprehensive treatment of the field.

The contribution that this series will make in encouraging interest in three-dimensional structure will be clearly derived from a broad experimental base. Descriptions of more speculative model building and conformational analysis will certainly not be excluded but there will be a major emphasis on identifying the assumptions which limit their significance.

The need to place such studies in some perspective would seem to be particularly timely since the rapidly increasing availability within many laboratories of high speed computers with good quality graphics can be expected to stimulate a great deal of work in this area.

The general level of treatment in this series is aimed at research workers in molecular biology and related fields. The major emphasis is on the results which have been obtained and the significance which should make these volumes of particular value to workers in cognate areas of applied biology and medicine.

VOLUME 1
TOPICS IN NUCLEIC ACID STRUCTURE
Edited by STEPHEN NEIDLE

Spring 1981 £20 c230pp ISBN 0 333 26678 1

This work systematically details the most recent data on all structural aspects of oligonucleotides, transfer RNAs, polymeric nucleic acids and chromatin. Each category is described both in terms of X-ray crystallographic and solution NMR data. A standardised and rational system of nomenclature is used throughout the book.

VOLUME 2
DEVELOPMENTS IN NUCLEIC ACID
STRUCTURE
Winter 1981 c£24 ISBN 0 333 31555 3

VOLUME 3 MOLECULAR ASPECTS OF ANTICANCER DRUG ACTION Winter 1981 c£24 ISBN 0 333 31556 1

MACMILLAN PUBLISHERS LTD

Contemporary thought on the quality of life and the evolution of society as influenced by current scientific theory and practice . . .

SCIENCE and ETHICAL RESPONSIBILITY Proceedings of the U.S. Student Pugwash Conference University of California, San Diego, June 19-26, 1979

Edited by Sanford A. Lakoff University of California, San Diego With the assistance of Jeffrey Leifer, Ronald Bee, Eric Markusen Foreword by Bernard T. Feld, MIT

A thought-provoking collection of papers by eminent scientists, scholars, public figures, and exceptionally talented young people. The contributions treat ethical problems in the relations of science to society in connection with:

Weapons technology

· Biomedical research

Technological aid to developing countries
The social effect of mechanization in agriculture
The role of scientific whistle blowers

Activities of scientists in political controversies

Among the senior contributors are such distinguished Among the senior contributors are such distinguished scientists and policy makers as George Kistiakowsky, science advisor to President Eisenhower; Jonas Salk, discoverer of the Salk polio vaccine; Herbert F. York, U.S. Ambassador to the Comprehensive Test Ban talks in Geneva; Clifford Grobstein, leading commentator on problems in bioethics; Roger Revelle, a major authority on population and development policy; three of the leading figures in the national debate over SALT II and arms control: Herbert Scoville, Jeremy Stone, and William van Cleave; and the Governor of California, Edmund G. Brown, Jr.

CONCEPTS of HEALTH and DISEASE: Interdisciplinary **Perspectives**

Edited by Arthur L. Caplan The Hastings Center and Columbia University H. Tristram Engelhardt, Jr., Georgetown University James J. McCartney, Georgetown University Medical Center and Biscayne College Foreword by Denton Cooley, Texas Heart Institute

The concepts of health and disease play pivotal roles in medicine and the health professions. This volume brings together for the first time the requisite literature for understanding current discussions and debates about these concepts. The selections in the volume attempt to present a wide range of views concerning the nature of the concepts of health and disease using both historical and contemporary sources.

Contents:

Health and Disease: Basic Interdisciplinary Reflections.
Historical Development of Disease Concepts. Disease versus
Values: Sex, Race, Addiction, and Sexual Preference. Disease
versus Values: Mental Health and Illness. Contemporary Analysis of Disease and Health. New Directions. Index.

June 1981, approx. 700 pp. Paperbound ISBN 0-201-00973-0 \$29.50

Prices quoted in U.S. dollars. Outside U.S.A. prices may vary somewhat from those listed reflecting distribution costs and currency fluctuations. Prices are subject to change without notice.

FROM CHANCE to PURPOSE An Appraisal of External **Human Fertilization**

Program in Science, Technology and Public Affairs University of California, San Diego

This book describes in language suitable for the general reader the background of the achievement of external human fertilization (in vitro fertilization), the nature of the procedures used, and the broad implications it has for the human future. The context of the discussion emphasizes the public policy issues and the required political mechanisms to reach sound decisions that will encompass both scientific advance and constructive social values.

To encourage the reader to responsibly address the issues stemming from the scientific achievement of human in vitro fertilization, this book:

Deals with the increasing impact of technology on human affairs and focuses on the history of deliberate intervention in human heredity and development.

Confronts the newly-heightened potential for external human fertilization and its more immediate consequences.

 Outlines ethical, social, and political issues associated with external human fertilization.

• Discusses the central issue of genesis of self and

personhood.Suggests an approach to policy-making which incorporates societal values with advanced scientific knowledge and technology.

Includes the full report of the Federal Ethics Advisory

Board that held extensive hearings on the issues in 1978-1979

April 1981, 223 pp., illus., with line drawings Paperbound ISBN 0-201-04585-0 \$17.50

CELLULAR IMMUNOLOGY Selected Readings

Edited by Vicki L. Sato, Harvard University Malcolm L. Gefter, Massachusetts Institute of Technology

This book is intended as an alternative or companion to a standard textbook for an introductory course in immunobiology. It is a collection of some of the original immunobiology. It is a collection of some of the original papers addressing fundamental questions in the area of cellular immunology and immunoglobulin genetics. Chapter commentaries serve to introduce basic concepts and to provide an overview of the papers in each chapter. Papers have been selected on the basis of the authors' teaching experience in the biology departments at Harvard and MIT. Their courses consist primarily of upperclassmen and firstyear graduate students.

Contents:

Early Studies on Cell Cooperation in the Immune Response. B Cells. Functional Diversity of T Lymphocytes. Suppression of Antibody Synthesis by T Cells. Tolerance. Macrophages and the Issue of Antigen Presentation. Antigen Recognition by T Cells. Thymic Education. Regulation of Antibody Synthesis: The Network Theory. The Molecular Biology of the Immune System.

September 1981, approx. 630 pp., illus., with line drawings Paperbound ISBN 0-201-10434-2 Price to be announced

T4 Polynucleotide Kinase from BRL is subjected to the most stringent quality control assays of any commercial supplier. T4 Polynucleotide Kinase is assayed for both:

- · deoxyribonucleases, and
- ribonucleases

However, the most convincing evidence of BRL® T4 Polynucleotide Kinase quality comes from its daily successful performance in the DNA and RNA sequencing reactions carried out in the BRL laboratories.

Indeed, RNA sequencing reactions demand the highest level of freedom from interfering ribonucleases. BRL® 74 Polynucleotide Kinase meets this level of quality, as shown in the following experiments:

- BRL® T4 Polynucleotide Kinase caused no detectable degradation of 5'[32P] -tRNAphe during a second extended incubation under non-exchange conditions
- Ribonuclease T1 (G specific) digestion of BRL® T4 Polynucleotide Kinase labeled tRNA^{phe} showed the sequencing ladder predicted from the literature 1.2. No secondary bands due to contaminating ribonucleases in either the T4 polynucleotide kinase or ribonuclease T1 enzymes were detected.

- Rajbhandary, U. L. and Chang, S. H. (1968) J. Biol Chem. 243; 598.
- 2. Wurst, R., Maxam, A., and Vournakis, J. (1978) Biochem. 17: 4493.

How Britain runs its Science

This highly successful wallchart, which first appeared in 1975, has now been completely revised and updated.

The 2×3 ft guide offers a comprehensive survey of the administration of British science. It provides a full account of the funding of science in Britain, giving details of money spent by government, research councils, industry and universities.

Designed as a fold-out sheet, it can be carried easily to meetings or hung as a wall poster for permanent reference. The new 1981 edition is available at £3.50 or \$7.95 by sending your cheque to either Nature's London or New York offices.

Only self-help for British universities

The Committee of Vice-Chancellors and Principals is right to have lobbied the British government last week with its argument that a slower contraction of the university system would help not merely the universities but the government itself (see page 281). But nobody should be surprised if the government chooses not to respond. For ever since it was announced nearly a year ago that the allocation of public funds to the University Grants Committee would be reduced over three years by 8.5 per cent, it has been clear that the agenda of the dispute between the government and the universities is partly a hidden agenda. The government is behaving as if large parts of the university system are effete, and that the time has come to teach them a lesson. In public, however, the government merely says that higher education must share in the sacrifices expected, at times of economic decline, by other publicly supported institutions. It would be better for all concerned if the hidden agenda were now made public. The plight of the universities is worsened because the British government's secret opinion of their usefulness is broadly based. The universities have long since lost the wholehearted friendship of the major political parties. Student rebellions in the 1960s, although modest by international standards, are well remembered. The rash of new undergraduate courses that came in at the same time helped to undermine the reputation of the university system as a whole. That many academics and institutions stood out against these excesses is forgotten, unjustly but understandably. And even though some of the surviving industries in Britain which owe their chances of future prosperity to graduates from the universities are quick to acknowledge their dependence, the public impression of the utility of the system is more accurately shaped by the numbers of graduates in sociology and related fields who leave their graduation ceremonies to join

The issue of academic tenure, the substance of the vicechancellors' complaint last week, is more contentious than the universities appear to understand. When the number of people unemployed in Britain is certain to increase above three million, it is hard to see emerging a wave of public sympathy for academics who lose their jobs. Indeed, the system of academic tenure is widely resented, even though it may be an essential assurance of freedom in scholarship - and, technically, required by the statutes under which many universities are established. Why should academics have a guarantee of lifelong employment when other people are being thrown out of work in droves? Against this public view, it would require a Hercules among ministers to persuade his colleagues in the British government to provide anything like a fund of £250 million to help academics see in the sunset years. Mr Mark Carlisle, Secretary of State for Education, is unlikely to fight for the vice-chancellors' case as they would wish. Such a fight would in any case expose him to the charge of maladministration — the muddle now emerging is, after all, one that he and his officials should have anticipated. Thus the most likely outcome of last week's meeting is that, for the time being, the government will let the universities stew in their own juice. If, in due course, the cost of academic redundancy threatens to loom large but the general level of unemployment has not declined, the government could think of overriding the provisions of tenure in academic contracts by means of legislation. As things are, the universities are virtually powerless. They have no choice but to seek out ways in which they can help themselves.

The first need is of self-help in the impending crisis. If the vice-chancellors' estimate of the number of academics likely to be

thrown out of work is anything like correct, the chances are that many people with a potentially important contribution still to make to scholarship and teaching will find themselves on a labour market in which their skills are not appreciated. Is it beyond the wit of the universities collectively at least to set up machinery for making sure that such displaced academics are not needed elsewhere in the system? And since all three parties to such an arrangement — the displaced academic and the two institutions between which he might be shuttled - stand to benefit, would not a fund to which all universities contribute help to smoothe the transfer of people between institutions? It is disappointing that the vice-chancellors seem so quickly to have abandoned hope that such schemes can function. It is also disappointing that they have not yet formally explored with the unions more radical departures from present arrangements — the replacement of annual by tenmonth contracts, for example, or the feasibility of a negotiated reduction of salaries, at least in the institutions most directly threatened. The sheer rigidity of the present arrangements, under which academic (and other) university salaries are nationally uniform and tightly linked with age is in itself one of the causes of present troubles. In present circumstances, there is every chance that a majority of university teachers would prefer flexibility and even hardship to the collapse of the institutions to which they belong. That chance should be explored, and quickly

Another immediate need is that universities should work out ways of sharing resources with each other. The University Grants Committee has pointed to some of the more obvious possibilities the pooling of equipment or the merging of departments between universities that happen to be close to one another. Other benefits could flow from joint appointments, the designation of some departments in some universities as places whose research equipment is regarded as a freely accessible pool. More important, in the contracting system there should be ways of pooling students, graduate students in particular. Some of the universities that survive the years ahead will be more lopsided than they should be. Some areas of study will have disappeared. Some departments, even whole universities, may find it necessary to give up in-house research. So the British university system, traditionally too indifferent to the need that students should have some freedom to explore different fields of study, needs to find ways of helping students as well as teachers move. And because it would be intolerable that students' chances of becoming graduate students should be determined by the chance that the university to which they happen to belong can keep its graduate programmes in being, there is an urgent need of national arrangements for placing bright people. This is a problem for the research councils.

It is not, however, too soon to ask what plans should be laid against the period after 1984-85, when last month's cuts have taken their full effect. For the causes of the present crisis will still then persist. Lacking coherence as a system and the capacity internally to be decisive even on academic policy, the university system of the late 1980s will be just as vulnerable as it has proved to be in the past few weeks. The most urgent need is that the system of public and private support for university education should be arranged in such a way that individual universities have a more explicit incentive to provide a valued service for their students and the communities in which they are embedded. Universities that are popular with students for good academic reasons should be helped financially — and not penalized (as the University Grants Committee is now threatening) if they attract more than their quota of home students. Good research, even as

0028-0836/81/300279-02\$01.00

crudely measured by the volume of successful research grant applications, should qualify for a bonus.

Breaking with tradition, the University Grants Committee should also make explicit the basis on which its allocations of funds are made, so that universities know how most successfully to compete for what funds there are. And something should be done to clarify, simplify and ideally cheapen the present cost to public funds of supporting students in universities. One of the causes of the government's discontent, and the immediate cause of the restriction on student numbers now announced, is the cost of paying student fees and maintenance grants, using local authorities as paying agents. These arrangements, dating back to the days when students were considered to be the salt of the earth, are certainly not the most economical ways of helping to encourage the spread of university education. The anomalies which they include are often inequitable as between one student and another. One of their consequences is that British universities are chronically short of student accommodation. The arrangements should be re-examined, whatever noise the National Union of Students makes.

But why should the universities take the initiative in helping the government to save money, when the government has been so beastly? That is a hollow argument. The objective is not economy but independence. For all its faults, the British university system is a remarkable and valuable institution. The most immediate danger is that it will be so demoralized by the three painful years ahead that its capacity for self-renewal will be permanently impaired, as will be its capacity to persuade those who must support it that even its present role, even in present circumstances, is indispensable. The most cruel irony is that the British university system has been so mindlessly attacked when it is more than ever apparent that Britain lacks many of the skills that the universities could cultivate.

Clinch River runs again

During President Carter's tenure at the White House, the fast reactor site at Clinch River in Tennessee seemed destined to become a special kind of white elephant — a collection of unused equipment surrounding a half-begun concrete structure that would for all time be a monument to the fancied folly of the 1960s that it would be possible economically to win power from a nuclear reactor making more fuel than it consumed. Now, the prospects are changing. Against expectations and the recent voting record of the key committees in the House of Representatives, Congress appears to be ready to see work at the reactor site begin again (see Nature, 16 July). President Reagan, having spoken fondly of Clinch River during his election, dutifully included in his budget in March a request to Congress for funds to start building again at Clinch River. But the issue has never seemed important enough to the Administration to justify the risks of a serious fight. In the end, local interests in Congress have given the Administration what it was asking for without blood being spilled. The embarrassment, for President Reagan, is that he must now ask the Department of Energy to brush up its policies in other parts of the domestic nuclear energy programme.

Although the completion of Clinch River has for some time seemed to be an acid test of the willingness of the United States to commit itself to fast reactor technology, appearances are false. The Clinch River design is more than a decade old; much has since been learned, especially in France, about the design and operation of fast reactors. The escalation of the cost of the project, by a factor of three or thereabouts, is a measure not so much of the optimism of its original designers as of the need for changes of design after construction had begun. The enforced four-year delay will not have helped. Clinch River may yet be a white elephant of a different kind, a representation of an earlier technology. Even so, it will provide some practical experience of the operation of nuclear reactors cooled by liquid metal (sodium). And it will be another spur to the continuing wrangle in the United States about the rights and wrongs of nuclear power.

Technically, Clinch River is a demonstration plant, intended to demonstrate to utilities and their customers that electricity can be produced safely from fast reactors and that, in due course, fast reactors could be built economically. The demonstration would have been more helpful if the design had been less out of date. But in the assessment the utilities will eventually have to make, one crucial piece of information will be missing. The economic case for breeder reactors of any kind (which need not be fast reactors) is that they can use plutonium as fuel. When President Carter took fright at the prospect of the "plutonium economy", the extraction of plutonium from spent fuel rods taken from existing reactors was suspended. The Administration's new and sensible policy on the proliferation of nuclear weapons (see page 281) will help to liberate the Department of Energy from the traditions of the recent past, but there is a lot to be done before the economics of the plutonium fuel cycle can be tested. Completing Clinch River will, however, be a nonsense if that is not quickly done.

The wider implications of Clinch River in the nuclear debate are not at this stage easy to foresee. The most serious argument in recent years against breeder reactors has been economic; the price of uranium has risen so much less quickly than that of fossil fuels, and the cost of electricity is so much less dependent on the cost of fuel in nuclear reactors than in fossil power plants, that the potential advantages of breeder reactors (fuel at no cost at all) are not worth striving for. So why not put the huge cost of development into more imaginative exploits? The argument is respectable, and deserves attention. Its flaw is its assumption that the relative prices of uranium and fossil fuel will remain what they are at present for two or three decades ahead. The snag, of course, is that the present price of uranium (about \$50 for a pound of uranium oxide) reflects the decline in the rate at which utilities have been ordering conventional nuclear plants in the past few years. If, as memories of Three Mile Island fade, and the lessons of that accident are properly learned, the utilities turn again to nuclear power as a source of electricity, the price of uranium would shoot up. Is it not, in such circumstances, prudent that there should be data about the operation of some breeder reactor that would allow sensible decisions to be made?

Less cogent arguments have been made by those who say that fast reactors are inherently less safe even than conventional nuclear plants. Anxiety of this kind stems from the observation that breeder reactors contain substantial amounts of fissile material, and that the neutrons involved in the nuclear chain reaction are fast and therefore, on the face of things, likely to complicate the control of fluctuations of reactor output. Neither argument is as persuasive as it seems, however. Weapons designers are always saying that their most serious problem is that of arranging that fissile material can be coaxed into some configuration that will explode, so that the risk that such a configuration will turn up by accident in a breeder core is likely to be small; certainly the risky configurations can with ingenuity be identified in advance; and steps can be taken to avoid them or to prevent the damage they would do. And anxiety about neutron speed should be offset by the relatively low thermal inertia of fuel elements in fast reactors and the high thermal capacity of the molten sodium. None of this suggests that there are no risks in completing Clinch River but merely that theoretical safety studies have probably now gone as far as they can.

The third foundation of the case against Clinch River, of which much will be heard in the weeks ahead, is that all nuclear reactors are an abomination and that fast breeders are a particular abomination because one of their products is plutonium, sometimes described as the "most poisonous substance on earth" and sometimes feared because it might be used for making weapons clandestinely. The arguments presuppose that neither the safety of nuclear plants nor the security of the material they produce can be held within reasonable limits. Yet even the colourful experience of Three Mile Island, essentially a demonstration that it is possible so seriously to damage a nuclear plant that it is virtually useless without scattering dangerous doses of radioactivity in the neighbourhood, cannot be used unambiguously to support the case against Clinch River and what might follow.

US revamps nuclear proliferation policy

Reagan's new plan: reactors for friends

Washington

President Reagan announced last week that he intends to shift the balance of US strategy back to a political rather than a technical approach for restricting the proliferation of nuclear weapons.

In contrast to President Carter, who sought non-proliferation objectives by threatening to withhold access to US nuclear materials and technology, Mr Reagan intends to emphasize "working to improve regional and global stability" and to use the influence which would be generated by the United States' role as a "predictable and reliable partner" in nuclear development.

He proposes to distinguish between different countries in the way in which non-proliferation policies are applied, a move which will please European and Japanese allies but could create problems elsewhere. Mr Reagan also said that his Administration "would not inhibit or set back civil reprocessing and breeder reactor development abroad"; but he added that this condition applied to "nations with advanced nuclear power programs where it does not constitute a proliferation risk".

This was a more moderate statement than some which the President made during his election campaign. The shift seems to have been due not only to a greater awareness of the complexity of non-proliferation, but also to the implications of the Israeli raid on the Iraqi research reactor, which Mr Reagan referred to obliquely in his statement when he talked of the urgency being "highlighted by the ominous events in the Middle East".

But the statement still gives critics of the Administration plenty to chew on. For example, the President announced that he intended strongly to support the efforts of the International Atomic Energy Agency (IAEA) in Vienna to provide an improved international safeguards regime. In particular, he said that the Administration would seek agreement on requiring IAEA safeguards on all nuclear activities in a nonnuclear-weapon state as a condition for any significant new nuclear supply commitment.

Doubts about the efficacy of IAEA safeguards procedures, however, linger on — particularly in the light of evidence provided to the Senate Foreign Relations Committee last month by ex-IAEA inspector Mr Roger Richter.

The Department of Defense, at least,

shares these doubts. In an inter-agency report submitted to the National Security Council, some of which was leaked to the Wall Street Journal last week, the Pentagon expressed doubts about the "weakness of the IAEA as an international institution", complaining of the agency's "lack of an intelligence capability and the limits of its scope and jurisdiction", and warned against "undue reliance on the IAEA by those responsible for national security". Administration officials insist, however, that international efforts to bolster the IAEA, including efforts to develop effective regimes for international plutonium storage and improved cooperation for spent fuel management, must remain central to any global non-proliferation strategy.

One significant deviation from Mr Carter's approach was Mr Reagan's announcement that his Administration intended to use the supply of conventional arms to allies as a way of reducing the motivation to acquire nuclear weapons. This argument has already been used to justify the offer of a five-year military aid package to Pakistan

Mr Reagan also announced that the White House would seek to persuade the Senate to ratify Protocol I of the Treaty for the Prohibition of Nuclear Weapons in Latin America, the so-called Treaty of Tlatelolco. This protocol, already ratified by the United Kingdom and the Netherlands, calls on nations outside the treaty zone to apply the "denuclearization" provision of the treaty to their territories in the zone.

The goal of the Administration's new policy, Mr Reagan said, was "to reestablish a leadership role for the United States in international nuclear affairs". He gave few clues, however, as to how the United States would punish countries which transgressed its guidelines, stating merely that his Administration would view a material violation of the Non-Proliferation Treaty and the Treaty of Tlatelolco as having "profound consequences for international order and United States bilateral relations". Similarly he said that the United States would "view any nuclear explosion by a non-nuclear-weapon state with grave **David Dickson** concern".

UK universities complain to government

A last-minute attempt to persuade the British government to change its mind about the scale on which university budgets are to be reduced was undertaken last week by the Committee of Vice-Chancellors and Principals. A delegation led by Dr Albert Sloman, chairman of the committee and vice-chancellor of the University of Essex, urged on the Secretary of State for Education, Mr Mark Carlisle, that it would cost less to arrange for a slower contraction of the system than to foot the bill for buying out the tenure contracts of academics now likely to lose their jobs. Dr Sloman said that he and his colleagues had been encouraged to hear Mr Carlisle say that he "now understood the problem".

The vice-chancellors' case is simple. University budgets will fall in the next three years by about 15 per cent because of reduced public subventions, the further loss of students from overseas and because the numbers of domestic students are to be reduced. The result is that university staffs will also have to be reduced - the committee's estimate is that 3,000 academics and 4,000 others will have to leave British universities. The direct saving to the government in the next three years will be £400 million, but the cost of buying out tenured contracts could well be £250 million. So the government would save money if the pace of contraction were 2.5 per cent a year, not twice as much.

The estimate of the cost of breaking contracts stems from legal advice the committee has been taking in the past few weeks. Where an academic's contract with

a university assures employment until retiring age (65), premature firing would expose the university concerned to a civil suit. Compensation for breach of contract might range from £40,000 to more than £100,000, according to age, salary and the courts' estimate that the academic concerned would find another job. One complication to come to light is that only 80 per cent of British university teachers are covered by such cast-iron contracts.

Dr Sloman and his colleagues wrung their hands last week over the prospect of endless unseemly legal battles with former academic colleagues. Court cases could take three years to settle. Although technically individual universities would be liable for damages, the vice-chancellors are counting on the government to implement a promise by one of its ministers that no institution would be driven into bankruptcy.

The prospect of mutual assistance within the university system seems, however, to be fading. The pooling of financial reserves (now estimated at less than £75 million) is unlikely to be appealing to the bestendowed universities, usually dealt with leniently in last month's cuts. Schemes for finding jobs for displaced academics at other institutions are likely to founder, according to Dr Sloman, on people's likely calculation that a court settlement would be more advantageous than a job elsewhere. Reducing salaries, or switching to 10-month contracts, would require negotiations with the trade unions for which there is no time.

The actual scale on which redundancies will occur remains to be determined. The committee's estimate of 3,000 academic redundancies is identical with that given by Dr Edward Parkes, chairman of the University Grants Committee, to a parliamentary committee earlier this year. Ministers at the Department of Education and Science are plainly sceptical about such large estimates. But Lord Flowers, vice-chairman of the committee and rector of Imperial College, said last week that not a single university institution in Britain would be able to avoid some redundancies before the next academic year is out.

The committee's calculations also suggest that the consequences of the decreed reduction of student numbers will be more serious than had been foreseen. Total numbers of home students are to be reduced from a peak of 272,000 (expected in the coming academic year) to 249,000 in 1984-85. This, the argument goes, will require that student intakes should be reduced from 78,000 (in the coming year) to 70,000 in 1982-83 and thereafter.

Salford University

Industry advertises

British industry has come to the aid of the University of Salford, the institution singled out by the University Grants Committee (UGC) earlier this month for the largest cut in grant and student numbers. Earlier this week, three leading manufacturing companies joined with the university in announcing the creation of the Campaign to Promote the University of Salford — CAMPUS. To launch the campaign, nearly 200 companies contributed to the cost of an advertisement in three national newspapers yesterday extolling Salford's virtues and calling for further support.

The scale and spontaneity of the support from industry suggests that UGC in deciding where the cuts should fall, may indeed have paid too much attention to grants awarded to universities by research councils and not enough to research funded by industry. The universities that are to suffer the largest cuts in their incomes, Bradford, Aston and Salford, are chiefly technological institutions, noted for their attempts to forge links with local industries. The UGC has told Salford that by 1983-84 its grant will be 44 per cent less than in 1980-81 and that it will have to cut student numbers by about 30 per cent. Although the university's arts faculties will suffer most, science and technology too will be cut drastically.

GEC-Marconi Electronics, Ferranti and Ward & Goldstone Ltd of Salford are the three companies that have taken the initiative in setting up CAMPUS. They say that the University of Salford has provided them with a steady stream of appropriately qualified graduates — GEC has employed 250 in the past seven years — has fostered

successful technology-transfer between university and industry and provides useful refresher courses for experienced technologists and managers. The local authority has also given support, especially to a new science park which is being established near the university campus in an attempt to revitalize manufacturing industry in the north-west of England.

The campaign has two aims: in the short term to convince UGC of the error of its decision and to persuade it to reinstate some of the grant it is taking from the university; and in the long term to foster closer cooperation with industry, in the running of the university. The campaign. however, is not a fund-raising exercise. according to Professor John Ashworth. vice-chancellor designate of the university. Professor Ashworth, who is in the embarrassing position of being chief scientist at the Central Policy Review Staff. the government's think tank, until he takes up the vice-chancellorship in September, hopes that, if the campaign's short-term aim fails, he will be able to call on the industrial supporters of CAMPUS for advice in restructuring the university.

Precisely what action CAMPUS takes in persuading the government and UGC of Salford's merits remains to be seen and will to some extent depend on the response to this week's newspaper advertisements. The other aggrieved technological universities are also being invited to join in the battle.

Judy Redfearn

Carcinogen regulations

Cleansing solution

Washington

Tension between the scientific staff of the US Department of Labor's Occupational Safety and Health Administration (OSHA) and their new political bosses came to a head last week, stimulated by complaints from the European-based International Agency for Research on Cancer (IARC) about the interpretation of data on the carcinogenicity of formaldehyde.

The dispute arose from a letter written by Dr Peter Infante, head of OSHA's Office of Carcinogen Identification and Classification, to Dr John Higginson, director of IARC, which queried the findings of an IARC working group that there were only "limited" data providing evidence of the carcinogenicity of formaldehyde on laboratory animals. Also included was a circular published last year by the National Institute of Occupational Safety and Health (NIOSH) describing formaldehyde as a carcinogen on the basis of various uncompleted studies with rats.

Dr Higginson complained that Dr Infante's letter appeared to "cast aspersions on the scientific integrity and objectivity" of the members of the IARC working group. And shortly afterwards Dr Infante was told by OSHA that he was

being fired for "insubordination" in sending his letter on official notepaper giving what the agency now describes as a purely personal opinion, as it is no longer prepared to endorse the conclusion that formaldehyde is, in fact, a carcinogen, and has withdrawn its co-sponsorship from the NIOSH bulletin.

Dr Infante's case is being seen as a symbol of the new Administration's determination to limit the powers of an agency previously accused of imposing a massive burden of regulation on the private sector. Already the director of NIOSH, Dr Anthony Robbins, has been dismissed by Mr Richard Schweiker, Secretary of Health and Human Services, as a "political activitist", and the Administration has also announced its intention to move NIOSH administrators out of Washington, a step which many agency officials feel is designed to weaken their effectiveness. Last Thursday the head of OSHA, Mr Thorne Auchter, was confronted at an angry hearing by Congressman Albert Gore, chairman of the House Science and Technology Committee's subcommittee on oversight and investigation, who described Dr Infante's firing as unacceptable political pressure on the work of scientists.

On the previous day, several highranking government scientists, including Dr Vincent DeVita, director of the National Cancer Institute, had agreed that data produced last year by the Chemical Industry Institute for Toxicology provided a "sound scientific basis" for suspecting that formaldehyde was carcinogenic in humans.

At the Thursday meeting Mr Gore produced a memorandum, written to Mr Auchter by his special assistant for regulatory affairs, describing the latter's meeting with representatives of the formal-dehyde manufacturers. At the meeting doubts were raised about the data on which the previous administration had based their description of formaldehyde as a carcinogen, doubts which Mr Gore suggested formed the basis of the decision by Mr Auchter to withdraw sponsorship of the circular issued jointly with NIOSH last December.

Dr Infante's immediate boss, Dr Bailus Walker, in his letter of dismissal said that OSHA "lacks confidence in the data" on which the circular, which has no regulatory impact but is meant primarily for information, was based. Dr Walker told Mr Gore that he had dismissed Dr Infante "on the advice" of his boss Mr Auchter.

Mr Auchter agreed that his decision that the carcinogenicity data were inadequate to support the conclusions of the circular, was made without consulting any of the agency's scientists. However, he insisted to Mr Gore that his lack of confidence was based solely on the use of the data for regulatory purposes, as conflicting data also existed.

Dr Infante's dismissal is now the subject

of litigation between himself and the agency, a fact which Mr Auchter initially used as a reason for not providing detailed comments on the case to the investigations committee. However, under pressure from the Congressmen, who presented legal advice that the hearings would not prejudice any later trial, Mr Auchter shifted his stance — and went on to deny that he had ordered Dr Infante's dismissal, directly contradicting the sworn testimony given by Dr Walker.

Dr Walker, who told the subcommittee members that "the data suggested that formaldehyde was a potential carcinogen and should be treated as such", has now resigned from OSHA to take up the position of director of public health for the State of Michigan.

The subcommittee has yet to announce the conclusions of its investigations. Indeed one minority member, Republican Congressman Robert Walker, sharply defended OSHA's actions on the grounds that Dr Infante had broken federal rules in representing his own scientific opinion as that of the agency. Mr Gore, however, was in no doubt "that the formaldehyde industry had "engineered a decision in the agency to change OSHA's view on the scientific data" and that this was behind the decision to fire Dr Infante.

David Dickson

Local DNA guidelines

Boston strikes out

Boston

In what could become a prototype for American cities seeking control of recombinant DNA research, the Boston City Council has passed a law regulating research at universities and commercial companies. The city ordinance follows community activism by residents of the Mission Hill district of Boston, who are concerned about the \$50 million grant by the Hoechst chemical company to the Massachusetts General Hospital and by the leasing of empty hospital space in their neighbourhood to Genetics Institute Inc., the newly formed genetic engineering company.

The city council hearings of the past month have actually been a repeat of events in nearby Cambridge eight years ago, when recombinant DNA research was entirely new. But on this occasion, there was less open conflict between citizens and university officials than in Cambridge.

The new law requires compliance with National Institutes of Health (NIH) standards but there are also further local restrictions which have been added since work began on the original proposal in late May. As well as assuring strict conformity with NIH guidelines, the ordinance demands:

• "Timely response to guideline amendment and permit applications in accordance with good governmental

practice".

- Research proposal not subject to NIH guidelines should receive council-administered permits.
- Broadening and restructuring of the Boston Biohazards Committee an area regulatory organization which will now serve as an advisory board to the commissioner of the Boston Department of Health and provide an annual report to the city council.
- Opening of normally confidential employee health records for "regulatory or public health study purposes".
- Institutions performing recombinant DNA research should monitor the health of their employees and the institutional responsibilities in this area should be "reasonable and related to potential risks".
- Costs of monitoring to be reimbursed to the city by the regulated institutions.

The final version of the ordinance left out the harshest requirement of the original proposal — that institutions should perform regular effluent monitoring and the testing for live organisms in the city sewer system. This was dropped because it is not technologically feasible.

In the past, local universities have agreed that guidelines of some sort would be helpful but have opposed the introduction of laws requiring compliance with official regulations, arguing that universities should set their own standards. But campus officials are generally pleased with the outcome of this debate and confident that they will easily meet the provisions.

The new ordinance will run for five years and is renewable. Several other cities in the Boston area and elsewhere in the United States have begun to review their own proposals for regulation as commercial companies are proliferating.

Michael D. Stein

Aspartame sugar substitute

New court overruled

Washington

It had been described as the first official attempt to resolve a complicated dispute over the safety of a new food additive by using a so-called "science court", with evidence on both sides being presented to a panel of three outside scientists. But last Wednesday the US Food and Drug Administration (FDA) overruled the verdict of its Scientific Public Board of Inquiry, reached after hearings held in January and February last year, and approved the marketing of a new low-calorie sweetener, aspartame.

Permission to market the sweetener had first been requested from FDA by its manufacturers, G.D. Searle, seven years ago. Initially FDA had agreed; but in the light of reports from a scientist at Washington University, St Louis, that the sweetener could produce brain lesions when fed to laboratory animals — and the general

concern that accompanied the decision to ban cyclamates in 1970 — permission was withdrawn the following year pending further studies.

Doubts about the validity of animal studies conducted for Searle to generate the data needed for new drug approval were discounted after two years of independent auditing of the studies. FDA then turned to the brain lesion claims, which were examined by a three-person team headed by Dr Walle J.H. Nauta, professor of neuroanatomy at the Massachusetts Institute of Technology. In their report, issued last October, the scientists said the data shown to them did not support the suggestions that aspartame might kill clusters of brain cells or cause other types of brain damage.

However, the "science court" also raised doubts about whether the reports of brain lesions could be completely discounted on the grounds that the tests had been carried out at doses far higher than those humans would normally experience. It recommended that marketing approval be withheld until further long-term animal tests had been carried out to rule out any possibility that aspartame could result in brain damage.

This conclusion was bitterly contested by Searle, already sitting on a stockpile of 300,000 lb of the sweetener, with a market value of over \$25 million. The company claimed that the three scientists' conclusions made "significant errors" in dealing with issues of tumorigenicity; and that they had "failed to employ biological and statistical principles that would have provided guidance in assessing the potential carcinogencity of a compound".

Searle pointed out that the sweetener is already being marketed in France, Belgium and Luxembourg, and that it has also been approved for use by the Joint Expert Committee on Food Additives of the Food and Agriculture Organization, and the World Health Organization.

The new FDA commissioner, Dr Arthur Hayes, now seems to have accepted Searle's arguments. Following the conclusion of the agency's Bureau of Foods that the "science court's" concerns were unfounded and that the sweetener would be safe even at the "highest conceivable levels" of consumption, he has agreed that it should be approved for use as a sugar-substitute and food additive, although not yet for soft drinks.

David Dickson

Environmental lead

Playing safe

Britain's health and environment departments seem to have won a victory behind the scenes in the government's decision last month to reduce the lead content of petrol from 0.4 to 0.15 g per litre. Other government departments concerned about the financial effects on the car and oil refining industries finally gave

way last May to the arguments that lead from car exhausts could damage the health of children in the inner cities. The environment and transport departments, however, supported the decision chiefly as a way of countering some of the increasingly fierce objections to building new roads.

The decision on lead in petrol came as a surprise just one year after a report commissioned by the health department concluded that there is no proof of a link between low blood-lead levels in children and impaired mental development. That report, prepared by a working party under the chairmanship of Professor P.J. Lawther of St Bartholomew's Hospital. was stimulated by research in Germany and the United States which implicated bloodlead levels as low as 35 µg per dl, now accepted as the maximum permissible by the European Commission. Although the working party concluded that these and other studies were equivocal, it recommended that steps be taken to reduce lead in food and water, seen as major sources, and air, a less significant source.

The Department of Health, however, seems to have persuaded the Department of Energy and the Treasury to act on petrol on the basis of evidence not covered in the Lawther report. A study by Dr R.G. Lansdown of the Great Ormond Street Hospital and Dr William Yule of the University of London Institute of Psychiatry of children in the Greenwich area of London is thought to have shown a correlation between low blood-lead levels commonly found in the British population and a slight impairment in IQ. That study, although made known to government officials, has not yet been published because of difficulties in interpreting data. Dr Yule now expects it to appear in the October issue of Developmental Medicine.

Other evidence which seems to have weighed in the decision includes the findings by the Greater London Council of exceptionally large quantities of lead in dust in some inner city playgrounds, research at ISPRA in Italy which suggests that 25-40 per cent of the total body lead burden may be contributed by lead in petrol and a critique of the Lawther report prepared by Professor D. Bryce-Smith and Dr Robert Stephens for the Conservation Society. The Conservation Society's document complained that the Lawther report did not pay sufficient attention to animal studies and that it underestimated the contribution of airbone lead by failing to allow for the fact that much of the lead in food and dust settles from the air.

The Department of Health seems to have persuaded the government to play safe by ordering the reduction. The search is still on, however, for better evidence of the possible effects of low lead levels on health. Dr Lansdown and Dr Yule are at present engaged on another study of inner city children and are discussing the possibility of a third, more extensive study with the Medical Research Council. Judy Redfearn

UK defence research

Slimming down

The Royal Aircraft Establishment at Farnborough, which with its several outstations is the largest of the in-house research stations run by the British Ministry of Defence, seems also to be the first in line for substantial reorganization. In the past year, the total staff of the establishment has fallen from 4,500 to 3,800. largely as a result of natural wastage (principally retirement) made possible by the top-heavy age distribution at the laboratory, itself a consequence of rapid recruitment during and immediately after the Second World War. But the remaining staff at the laboratory are now anxious that attrition has a lot further to go.

The establishment is the most conspicuous of the defence research establishments considered by the internal government review under Lord Strathcona, whose report has not been formally published but has instead been placed in the library of the House of Commons, where its presence is almost certain to have the most damaging consequences. In respect of Farnborough, the report recommended that further consideration should be given to the need for maintaining three airfields (at Farnborough, Bedford and Boscombe Down), a balloon station (at Cardington), three missile ranges and a variety of wind tunnels that (in Lord Strathcona's view) could well be hived off to private contractors.

At a meeting at Farnborough on 4 March, the director of the establishment, Mr T.H. Kerr, told the staff that the future of these offshoots was being considered by a series of working parties, and that decisions would be made later in the year. The most obvious possibility of change is that missile ranges may in future be managed by private contractors (as is to a large extent already the case at the Welsh firing range at Aberporth). But there are also to be rearrangements of the internal divisions at Farnborough (leading to the loss of relatively senior staff) and the future scale of operations at the establishment has not yet been determined, which is why some members of staff fear that their director's promise (on 4 March) that reductions could be accomplished by retirement, early retirement and other wastage (as well as the transfer of some staff to private contractors) may not be feasible

The chief source of anxiety in the past few weeks, however, is strictly speaking hardly relevant — the steps being taken by private interests in case the Farnborough airfield is eventually put up for sale. It seems to have been decided that, if any of the three airfields is to be sold, the sale of Farnborough would cause the least damage even though the establishment would wish to retain the right to mount the biennial air show of the Society of British Aerospace Companies on the site. The bid to purchase

New Forest flutter

In the name of science, lepidopterists have for many years, chloroformed butterflies to death and displayed them in glass cabinets. Now many of those butterflies are increasingly imperilled by loss of habitat, killing by insecticides and other hazards of the twentieth century. A cautious welcome then, for Britain's very first public "butterfly farm", which opened yesterday (22 July) in the New Forest. It's not being run for the good of science though, simply as a tourist attraction to bring in money to an estate at Ashurst, near Southampton.

There should be more than 1,000 butterlies at Ashurst if the breeding programme is successful, flying freely in a glasshouse covering 6,750 square feet.

Now in Hampshire - the American monarch

Over 50 different species will be on view, mostly colourful imports from the tropics, including the North American monarch, *Heliconius* from South America, swallowtails from South-East Asia, and the Camberwell beauty.

Like all would-be "tourist traps" the farm boasts a gift shop. Books on butterflies will be on sale, of course, but so too will live caterpillars and pupae, presumably to encourage butterfly farming as a hobby. Traditionalists are also catered for, they can buy mounted butterflies.

None of this is likely to do any direct good to the average butterfly in the street, or field. But the "farm" owners reckon that by increasing the public's awareness of what they call "these delicate creatures", life will gradually improve for what's left of Britain's butterfly population.

Charles Wenz

the airfield is based on the hint in the Strathcona Report that the airfield would be suitable as a base for business flying, but will not be considered until all the working parties considering the future of the defence research establishments have had their way.

Last week, at another staff meeting, Mr Kerr had little extra to say. Discussions have begun with potential operators of the parts of the establishment to be hived off, but firm proposals are not expected until early next year. Bidders for these contracts (among which British Aerospace is conspicuous) are being asked to take over existing members of the staff — and unions such as the Institution of Professional Civil Servants are looking for an assurance that their members' terms of employment will not be adversely affected.

French energy policy

The great escape

There were two striking omissions from the roster of nationalization proposals announced by the Prime Minister of France, M. Pierre Mauroy, recently — Framatome and Novatome, the companies which between them account for almost the whole business of constructing conventional and fast breeder reactors in France. The exceptions are remarkable because the Socialist Party had announced before the election that all industries concerned with the nuclear fuel cycle would be nationalized.

M. Mauroy was, however, quite clear in what he said: eleven groups would be nationalized, not one more nor one less. The omission of the nuclear industry is another indication that the new government does not intend seriously to disturb France's growing lead in nuclear technology. Mauroy explained that the companies to be nationalized are included in his list not for doctrinal reasons but to improve their competitive performance as has been done with the car maker Renault. (In fact the new Minister for Industry, M. Pierre Dreyfus, was previously managing director of Renault, so his appointment has somewhat comforted industrial opinion.) Thus the immunity of the nuclear business amounts to a tacit recognition of its independent commerical success.

The grand debate on energy also begins to look less of a confrontation than a few weeks ago. It is expected now to take place in the National Assembly in November — and instead of focusing on nuclear power it will look at all aspects of the energy question, a difficult matter in what will be a packed legislative session. Parliamentary and specialist groups have been set up to investigate separate issues.

Anticipating the debate, M. Mauroy has seen fit to announce the broad outlines of French energy policy. The two priorities will be to develop indigenous fossil fuel production, insofar as that is economic (taking account of world prices) and to pursue a significant nuclear programme.

Mauroy did not mention renewable sources or even conservation, and his remarks on fossil fuel production are taken to imply caution in the further development of France's costly coal compared with the cheaper Australian product. That leaves, of course, nuclear power as the central plank of his energy policy.

On this reading, the government must arrange that the November energy debate will lead to a vote to continue to build new pressurized water reactors. (New starts are temporarily suspended.) The construction of Superphénix, the commerical demonstration fast breeder reactor, continues, and a decision on a second one can be comfortably left for a while.

Mongolia's jubilee

Following the lamas

The Mongolian People's Republic this month celebrates the diamond jubilee of its foundation on 11 July 1921. Included, de facto, in the anniversary is the Mongolian Academy of Sciences, since although formally inaugurated only in May 1961, it originated, in the words of Dr B. Shirendyb, president of the academy, from "a small group of scientific workers" who banded together immediately after the establishment of the Republic to raise the scientific standards of the country.

Not that science had been entirely neglected in pre-revolutionary Mongolia. An astronomical observatory had been founded in Ugra (now Ulan Bator) in 1779, and a flourishing medical tradition was preserved in the lamaseries. Nevertheless, in the early years of the new state, the major task was the translation of basic scientific texts from Russian and other European languages. And before even this could be done a more fundamental problem had to be solved of replacing the picturesque but impractical traditional script by a modern alphabet.

Astronomical observatory Mongolian style

Inevitably, present day research in Mongolia is largely directed towards the needs of the economy. During the past five years, the various institutes of the Academy of Sciences carried out 369 research projects, which should ultimately save the economy more than 108 million tugriks (£18 million). Research included the use of methods of nuclear physics in surveying the country's deposits of copper, molybdenum and tungsten, mapping of seismic zones, the extraction of pharmaceuticals from traditional medicinal herbs, and the development of new strains of wheat and breeds of sheep.

International help has not been lacking. The plan to establish a 5 million hectare nature reserve in the Gobi Desert is receiving considerable assistance from the United Nations Environmental Programme, and Comecon countries have some 60 joint research projects in operation with Mongolia. One piece of research, not yet covered by a formal agreement but watched with considerable interest by Mongolian scientists, is the work of Dr Tibor Farkas at Szeged

(Hungary) on the biophysics and biochemistry of frost damage. The Mongolians hope that this work will result in the development of an anti-frost spray for spring wheat, which is at considerable risk in their harsh climate.

Among the facilities that Mongolia has to offer its international collaborators is the Gobi Desert — a valuable hunting ground for Comecon expeditions in search of fossils of dinosaurs and dinosaur eggs.

Vera Rich

Belgian scientific institutions

Arresting decline

Brussels

It has long been felt in Belgium that some of the country's most renowned scientific institutions are falling into decline. Disaffection is so great that last spring the staff of eight major institutions resorted to strikes to draw attention to their grievances. Now at last the government has decided to do something.

A committee of wise men has been given the task of finding ways to unravel the administrative snarks which are held responsible for the problems. The eight institutions under review are the Royal Library of Belgium, the National and Provincial Archives, the Royal Belgian Institute of Natural Sciences, the Royal Museum for Central Africa, the Royal Belgian Observatory, the Royal Belgian Meteorological Institute, the Belgian Institute of Aerospace and the National Centre for the Production and Study of Microbiological Substances.

The problems of these institutions are uniquely Belgian. When the constitution was revised in 1970, it was decided to keep them as national bodies. The conflict between the Flemish and Walloon (French-speaking) communities in Belgium has led to a virtual duplication of all administrations and much else. The education system is completely divided along linguistic lines. As national bodies, the eight institutions in question fall foul of the system and do not benefit from the patronage of either the French or Flemish education ministers.

Every decision has also to be approved by three or four ministries and with a change of government every few months, the national institutions have found it very difficult to get anything done. Most of the directors of the institutions have left in disgust at the administrative confusion.

The committee is due to make its first report within the next three months, but the recommendations are bound to involve more drastic cures than simple administrative pruning. Some of the institutions with more active research departments are sure to be merged with universities. And the worrying size of Belgium's public-sector deficit may prompt the committee members to recommend that parts of the institutions should be axed completely.

Jasper Becker

CORRESPONDE

Radical writings

SIR - Dr Turner's letter (Nature 4 June, p.374) makes the disturbing claim, citing the exchange between Dawkins and myself as evidence, that "the radical scientific opposition to racism requires a denial that there is any genetic variation of any significance from place to place within the human species". I wonder what on Earth he has been reading which provides support for such an assertion? As someone who has been reading, writing and teaching in this area for some years now, I can't remember ever seeing such a claim, and I would be interested if he could produce a single statement from the writings of "radical" biologists since the sociobiology and IQ debates started in the late 1960s which could support his allegation.

The Open University. Milton Keynes, UK

Australian 2,4,5-T

STEVEN ROSE

Sir - Since you published our letter on "Antipodean 2,4,5-T", a sample of the herbicide imported into Australia has been brought to our attention. It had been submitted to the Australian Tariff Board by the importer as a sample of a very large consignment on which lower tariffs had been sought. It was recently analysed by the West Australian Government laboratories and found to consist essentially of the isobutyl ester of 2,4,5-T, and to contain 19 mg per kg of 2,3,7,8-TCDD on an "as received" basis, and 26 mg per kg on a 2,4,5-T basis. (The level of TCDD (2,3,7,8-tetrachlorocyclodibenzo-pdioxin) in 2.4.5-T considered acceptable in Australia at the time was 0.1 mg per kg.)

Evidence given before the Tariff Board inquiry suggests the material may have been produced from fire-damaged potassium trichlorophenolate (KTCP). [A synthetic route to 2,3,7,8-TCCD is through the heating of KTCP^{2,3}.] A letter from the Singapore High Commission (Australia) has confirmed that a fire occurred in the premises of the importer's Singapore company, and pointed out that (1) there were reports of chloracne in the factory workers and (2) after the fire, the neighbouring factory complained of symptoms in its workers. The importer himself described this "fire damaged" material as of "good value"4, and so one assumes that it entered commerce in Australia.

All of this makes more pressing our concern for Australia's epidemiological inquiry into Vietnam veterans' claims. Use of 2,4,5-T with such high levels of TCDD can prejudice the controls in this study. It will also have implications for ordinary civilian usage.

We hope that one result of our work will be that the Australian authorities will increase their surveillance of chemical imports.

Conservation areas

Sir — It would seem injudicious for Dr Ratcliffe to claim1, as his guarantee of rightness, the wisdom of Parliament when a minister of the Crown can say2, after receiving the advice of the Nature Conservancy Council (NCC) "I welcome the international recognition that it is totally unacceptable for species to be allowed to disappear", though this is quite in keeping with the NCC's concern to safeguard Sites of Special Scientific Interest (SSSIs) "in perpetuity". If the NCC has not got the financial resources to provide invariable, immediate and adequate compensation to the owners of SSSIs, how will their perpetual preservation policy prevent glacial readvance over the Black Wood of Rannoch, or pluvial destruction of the Pennine limestone pavements, or, perhaps, provide fall-out shelters for Dartford warblers?

I suppose that one must expect if one has the temerity to express an unfashionable point of view that one will be misunderstood accidentally and deliberately^{3,4}, so may I make it clear that I am not advocating the wilful destruction of anything, organism or habitat, but I do feel that anyone, acting as a scientist, needs a better excuse that a personal predilection for the rare, the exotic, or the status quo before he asks people to forgo the benefits of cultivating their gardens or puts others to the national expense of compensating them for their abstinence. I had been led to believe that science was an organized body of knowledge concerned with the physical world as we find it, static or dynamic as the case may be, that scientists were by their training perhaps better equipped than most to make reliable predictions of the likely outcome of the processes which they observe, but that as scientists they have no claim to superior knowledge or wisdom in prescribing what goals or courses of action are desirable on moral, political or economic grounds. It is against this assumption of authority, which is more than hinted at in Dr Ratcliffe's last sentence, that I am railing.

Israeli raid

Sir - I was unpleasantly surprised to read the leading article in Nature entitled "Making Israel atone for Tamuz" (18 June, p.523). I and many others of your readers are of the view that Nature is a scientific journal, which justifiably includes articles on scientific or educational policy in addition to the research material which it publishes. However, this was an article of a purely political nature, written about a very sensitive issue without any backing of specialized knowledge. It was in my view an unwise decision to publish such an article in Nature and a dangerous precedent.

It is, of course, impossible to enter into a full discussion with you on the reasons for Israel's decision to bomb the nuclear plant in

Iraq, but there are certain facts which have been ignored in this article, which should be brought to your attention.

- (1) There is a great deal of evidence that Iraq has ambitions to acquire a nuclear weapon and it has built up its military power in the last few years to an alarming magnitude. As this country is at war with Israel, having consistently refused to enter into any peace negotiations, this must be a serious threat to the security of Israel.
- (2) To ask Israel to accept the report of the UN International Atomic Energy Agency is expecting a lot, in view of the attitude of the United Nations and its agencies towards Israel in the past. If Israel is to survive it must depend on its own intelligence assessments. This is exactly what it did in this case, and it acted before it was too late.
- (3) The article ignores the fact that Israel has never refused to enter into peace negotiations with its Arab neighbours. Except in the case of Egypt these countries have not only refused but quite openly proclaimed their ambition to destroy the State of Israel; Iraq has been one of the leading advocates of this policy. Under these circumstances how can one expect Israel to enter into a "Non-Proliferation Treaty"?

ANNE BELOFF-CHAIN Imperial College of Science and Technology. London, UK

Forbes, not Wallace

SIR — In his review of a recent symposium on biogeography, Colin Patterson regards A. R. Wallace as the inventor of "biogeography in the accepted sense", and gives the impression that he thinks very little of the scientific competence of Charles Darwin in this context (Nature, News and Views 25 June, p.612).

I refrained from joining in the previous arguments in your columns about cladism, evolution and Darwin, but in this instance I must protest that in enthroning Wallace and demoting Darwin, Dr Patterson is overplaying his hand and ignoring the earlier literature. Darwin was well aware that the continents were not immutable (see the sketch of 1842 and the essay of 1844), and that previous epochs may have had land connections different from those of the present. It is incorrect to claim that evolutionary hypotheses based on unchanging continents dominated biogeographical thinking up to the 1960s, when Wegener's views were finally accepted by orthodox geophysicists. Many of the published biological arguments of the period were about the extent and timing of the land and sea connections, not whether they

Darwin was also aware of contemporary studies of geographical distribution, such as the excellent review of Edward Forbes, not mentioned by Dr Patterson, published in the first volume of the Memoirs of the Geological Survey, 1848. In this article Forbes clearly stated an hypothesis for a previous land connection between the Iberian peninsula and Ireland. If anyone is to be selected as the father of biogeography it should be Forbes.

NEWS AND VIEWS

Ocean currents and wind: how well can the connection be made?

from Charles C. Eriksen

A recent issue of the Journal of Geophysical Research (86, C3, 20 March 1981) contains two articles which serve to demonstrate the wide gulf between observations and models of wind-driven ocean response. The paucity of reliable upper ocean measurements and suspension of Ekman dynamics make the situation even worse near the equator. One article, by S.G.H. Philander and R.C. Pacanowski, describes the results of a numerical simulation of the response of a stratified equatorial ocean to periodic wind forcing at periods from days to years. The other, by R.A. Weller, describes current profiles made at mid-latitude from a drifting research platform. While Philander and Pacanowski make rather detailed predictions of oceanic response, Weller finds that Ekman theory, a cornerstone of dynamical oceanography (W.V. Ekman in 1905 predicted current profiles which spiral and decay with depth through a balance of frictional and rotational forces in response to wind stress at the surface), fails to account for the rather weak decay of shear away from the surface which he observed.

The problems of measuring in the upper ocean are formidable. It is only recently that instruments have been developed which succeed in removing the contaminating effects of surface waves on current measurements. This success is achieved by utilizing linear sensors which can deal with currents which are not confined to the horizontal plane. The time scales of wind forcing and ocean response make sequential measurements at one or more fixed locations an attractive method of examining ocean physics. These eulerian descriptions of the flow are often collected from current meters tethered at fixed depths along a deep sea mooring. Weller used newly developed current meters in a profiling mode, raising and lowering them by winch from the uniquely stable Research Platform Flip (a giant spar buoy resembling a submarine tipped on end, which pitches and rolls hardly at all). Since Flip drifted modestly, the measurements are not eulerian, but their excellent accuracy allows records of current shear to be compared with time-dependent Ekman

models. Although the observed changes in phase with depth are modelled by simple Ekman dynamics at most frequencies, the amplitude structure is not. The discrepancy ultimately seems to be nonlinear. Turbulence produces apparent diffusivities which greatly exceed molecular values. The spatial structure of eddy viscosity (turbulent diffusion of momentum) is poorly known, as is the role of larger-scale nonlinearities in the flow. These two unknowns keep upper ocean response to wind stress in the class of 'fascinating unsolved problems' in oceanography and promise to do so for some time in the future.

Near the equator, Ekman theory breaks down because the horizontal Coriolis forces associated with the Earth's rotation vanish. There is no satisfactory theory for the planetary boundary layer at low latitudes; most theories use a body force formulation (stress distributed a priori in a slab of water) to circumvent this problem. This arbitrary linkage is used to provide a forcing mechanism, to which the response by large-scale ocean dynamics is sought. Numerical models are often the only means by which the complicated effects of density stratification, friction, nonlinear effects and ocean boundaries can be considered together. In the equatorial oceans it is clear that all of these effects are important. Everyone seeks simple force balances, and discarding one or more of these effects in favour of the others is a popular method of equatorial theorists. Unfortunately, largely for technical reasons, there is relatively little guidance from observation for the correct choice in a given situation. Numerical studies also require data taken at discrete intervals to keep computations manageable (even the largest computing facilities can be easily overburdened by the size and density of calculations demanded by modest models of ocean circulation). The resulting simulations are not altogether realistic, but at least describe the mechanisms at work in different flow regimes. Philander and Pacanowski state various results about how the ocean responds to wind forcing, but it should be remembered that these are the results of a model study of a numerical ocean which one cannot be sure behaves exactly as the real oceans do.

The results Philander and Pacanowski report are an example of what can be said about oceanic response from an incorporation of the general effects, but not the details, of the mechanism by which wind energy is transferred to the ocean. They highlight the unique character of equatorial oceans — that it is possible to have a Kelvin wave trapped to the equator which can carry energy eastwards, in addition to equatorial analogues of the long Rossby waves at mid-latitude which carry energy to the west. Philander and Pacanowski identify three ranges of period: (1) at the short periods (a few days) strong currents are not generated, but rather a spectrum of equatorial waves; (2) at intermediate periods (weeks, months) upper ocean currents are generated primarily which reflect off the basin boundaries in a complicated fashion; and (3) at very long periods (greater than several months to a year or more, depending on the basin size) steady-state response is achieved. The nonlinear nature of the problem causes Rossby waves to be modified by the mean currents at low frequencies. Also, rays along which energy travels have shallow inclinations at long period, so that the deep ocean can only contain wave energy which is the result of one or more reflections off the basin ends. There are very few measurements by which any of the predictions of the model can be tested; however, the general contrast between observations in a small basin and a large one (Atlantic versus Pacific) tends to confirm the predictions of the model. It is a big job to observe enough of the ocean to really test these models in even the most rudimentary way. At this point large-scale theories are far more sophisticated than data. Observations are needed to verify the assumptions upon which the models rest, as well as the general model results.

Charles C. Eriksen is in the Department of Earth and Planetary Sciences at the Massachusetts Institute of Technology.

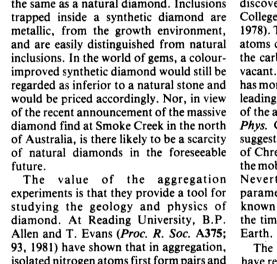

Migrating nitrogen atoms in diamond

from Gordon Davies

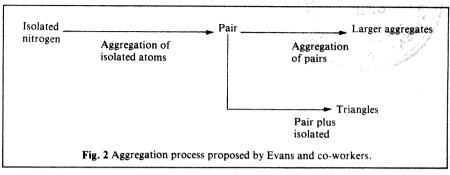

By crystallographic standards gem quality diamonds are highly impure. Most of them contain nitrogen at about one part in a thousand — some 10²⁰ atoms of nitrogen per cubic centimetre of diamond. Significant colouring is usually produced in a crystal when it contains about 1017 impurity atoms per cubic centimetre, but natural gem diamonds are usually colourless because the nitrogen atoms have aggregated into pairs, each pair replacing two carbon atoms. The paired form does not absorb visible light as its absorption bands lie in the ultraviolet part of the spectrum. However, if even a small fraction of the nitrogen is present in the simplest form, as isolated nitrogen atoms with each atom replacing one carbon atom, then an unattractive brown colour is produced. Most synthetic diamond is of this type and is unsuitable for use as gem stones.

In nature many diamonds are also found in which the nitrogen aggregation has gone further, producing aggregates of three or more nitrogen atoms (see Fig. 1). Diamonds like these are often of considerable commercial value as gem stones, for in a triangular arrangement the nitrogen can absorb near-ultra violet radiation and emit the energy in the visible part of the spectrum, enhancing the brightness of the diamond in a whiter-thanwhite effect.

In the early 1970s Soviet science journals reported that synthetic diamonds grown at higher temperatures and pressures than usual had a small amount of their nitrogen in the aggregated forms typical of natural diamonds, although most of the nitrogen was still scattered through the lattice as isolated atoms. A few years later, at the General Electric Corporate Research and Development Laboratories in Schenectady, New York, R.M. Chrenko, R.E. Tuft and H.M. Strong observed substantial aggregation of the nitrogen in some of their own synthesized diamonds when the diamonds were heated to about 2,000K for 30 minutes. In one diamond they converted three-quarters of the isolated nitrogen atoms into aggregated forms. The technique was published in Nature (270; 141, 1977) and protected by patent (British Patent specification 1578987).

isolated nitrogen atoms first form pairs and then migrate to produce the larger aggregates (see Fig. 2). The longer the diamond is held at a high temperature, the further the aggregation proceeds, so the state of aggregation in any diamond gives some idea of the length of time it has been heated. The temperature at which natural diamonds grew can be measured independently from the chemistry of their inclusions; for all diamond sources a temperature of about 1,450 K is indicated (J.J. Gurney and B. Harte Phil. Trans. R. Soc.

The possibility of improving the colour of synthetic diamonds may appear to have commercial implications for the gem industry. In practice, however, the cost of growing gem-sized diamonds is prohibitive, and to convert any nitrogen in the diamond requires a further heat treatment at the aggregation temperature of 2,000 K. The processed diamond would still not be the same as a natural diamond. Inclusions

A297; 273, 1980). Extrapolating the

laboratory results of Chrenko et al. down to this low temperature, Allen and Evans estimate that those rare natural diamonds containing only isolated nitrogen atoms must have been ejected to the surface of the Earth within 50 years of their growth — a very short time scale geologically.

The accuracy of this estimate is currently unknown because of a complication discovered by A.T. Collins at King's College, London (J. Phys. C11; L417, 1978). The speed at which isolated nitrogen atoms can migrate is increased if some of the carbon atom sites in the diamond are vacant. A nitrogen atom next to a vacancy has more room to manoeuvre in the crystal, leading sometimes to a 50-fold acceleration of the aggregation process (A.T. Collins J. Phys. C13; 2641, 1980). Collins has also suggested that the original measurements of Chrenko et al. may have overestimated the mobility of the isolated nitrogen atoms. Nevertheless, when the migration parameters of the nitrogen atoms are known better it will be possible to fix the time a diamond has spent deep in the

The nitrogen aggregation experiments have recently cleared up one long-standing problem of diamond research. Many natural diamonds contain twodimensional defects, with diameters of the order of tens of nanometres, lying in their cube planes. These 'platelets' only occur when the diamond contains a large concentration of nitrogen. During the 1960s it was generally assumed that all the nitrogen was tied up in the platelets. Then E.V. Sobolev, V.I. Lisoivan and S.V. Lenskaya (Sov. Phys. Dokl. 12; 665, 1968) showed that there was no simple correlation between the number of platelets in a diamond and the concentration of nitrogen it contained. During the 1970s it was found that the optical properties of diamonds could be satisfactorily explained if the platelets were simply ignored, and the nitrogen assumed to exist only in small aggregates like the pairs of nitrogen atoms. But now, T. Evans, Zengdu Qi and J. Maguire (J. Phys. Gordon Davies is in the Wheatstone Physics

Laboratory, University of London King's College.

C C \mathbf{C} C C \mathbf{C}

Fig. 1 Highly schematic diagrams of the smallest nitrogen structures in diamond: a, the isolated nitrogen atom, b, the nitrogen pair, c, the nitrogen triangle. In the nitrogen triangle, the N atoms share one common C atom as the nearest neighbour; they are not bonded directly together.

C14; L379, 1981) have produced platelets in a synthetic diamond solely by heating at 2,700 K for 4 hours and at 2,800 K for 2 hours. Initially, the diamond contained about 10^{20} cm⁻³ isolated nitrogen atoms. After the heat treatment some 10^{15} cm⁻³ platelets with diameters of 20–50 nm were produced — equivalent to about 2×10^{19} cm⁻³ defect atoms — as well as the other aggregated forms of nitrogen which accounted for some 10^{20} cm⁻³ nitrogen

atoms. The experiments can only be understood if the platelets are made of nitrogen. The apparent discrepancy in the numbers above is expected since the distribution of nitrogen in synthetic diamonds is inhomogeneous.

The picture emerging for the 1980s of nitrogen in diamond is that it is present in both the platelets and in the atomic-sized structures. Key experiments are required to complete the picture: accurate calibrations

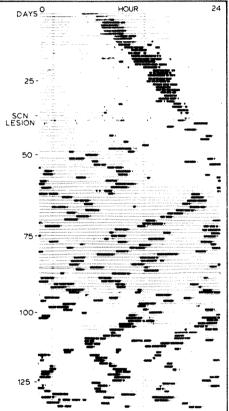

have to be made so that the concentration of nitrogen in each structure may be measured easily; the thermodynamics of each stage of the aggregation have to be found; and ¹⁵N isotope shifts in the optical features of the platelets could establish more about the role of nitrogen in the platelets. Although much still has to be done, the migration of nitrogen in diamond is turning out to be an extremely profitable line of study.

Are the suprachiasmatic nuclei the location of the biological clock in mammals?

from Fred W. Turek

Over the past twenty-five years, largely due to the efforts of Colin Pittendrigh and Jürgen Aschoff, it has been demonstrated that the generation of circadian (that is, approximately 24-hour) rhythms in animals depends on an internal biological clock. The endogenous oscillator is normally synchronized by environmental factors, principally the photoperiod, to the 24-hour rotation of the Earth upon its axis. Hundreds of circadian rhythms have been described and the formal properties of circadian systems analysed. Recently, attention has switched to the location of the biological clock(s) and the mechanisms by which the clock is coupled to the many rhythms it drives. Hundreds of experiments in scores of laboratories around the world have been carried out in an attempt to elucidate the neural elements involved. However, it is only within the past few years that the neuroscience community has begun to apply the entire armamentarium of neural techniques to the study of circadian rhythms. These initial studies have already yielded a number of important findings and have laid the groundwork for future work involving the search for the circadian clock in animals.

In mammals, the hypothalamic suprachiasmatic nuclei (SCN) have become the centre of attention. Compelling evidence that this region of the hypothalamus plays an important part in circadian organization was first provided by Stephan and Zucker¹ and Moore and Eichler² when they discovered that destruction of the SCN in rats altered both the entrainment by light/dark cycles and generation of circadian rhythms. Since these pioneering studies, many researchers have observed that bilateral lesions of the SCN in rodents disrupt a variety of circadian rhythms including drinking, eating, locomotor behaviour, plasma corticosterone, pineal N-acetyltransferase activity, sleep, heart rate and body temperature. In addition, SCN lesions disrupt oestrous cyclicity and photoperiodic time measurement, two parameters which depend on the circadian system for temporal information3.

Continuous record of the wheel-running activity of a male hamster maintained in constant light. Successive 24-hr days are plotted from top to bottom. On day 37 of this record, the animal received a bilateral lesion of the SCN which resulted in a clear disruption of the normal circadian rhythm of locomotor activity (from G.E. Pickard and F.W. Turek, unpublished results).

Since it is now quite clear that multicellular organisms are made up of a population of circadian oscillators, the search for the biological clock is really the search for that clock or system of clocks which coordinates the various internal oscillators with each other and the outside environment. Evidence for the existence of a population of oscillators comes from many different experiments including some that involve the destruction of the SCN in rodents. Early studies indicated

that lesions of the SCN resulted in the complete loss of entrainment and the abolishment of free-running circadian rhythms but more extensive studies by Rusak4 in the golden hamster suggested that a variety of independent rhythmic oscillators exist in the absence of the SCN. The figure shows the dramatic effect that lesions of the SCN can have on the circadian rhythm of locomotor activity in the hamster. On some days (for example, days 87-96) no rhythmic pattern is obvious, while on other days bimodal (about 12 hr: for example, days 100-111) and trimodal (about 8 hr: for example, days 113-120) activity patterns are generated. Rusak postulated that such patterns indicate that circadian oscillators continue to function in these animals, but the SCN are necessary to integrate these oscillators into a single circadian framework. Further evidence that at least some circadian rhythms persist in mammals after destruction of the SCN comes from work on squirrel monkeys. Although the circadian rhythms of behavioural activity, feeding and drinking are abolished following bilateral destruction of the SCN, the rhythm of body temperature persists⁵

Attempts have been made to locate the endogenous biological clock by determining the pathways which connect the environmental factors, principally light, to the entrained circadian system. A direct retino-hypothalamic tract (RHT) which terminates in the SCN has been observed in many mammals6 and it has been suggested that this is the primary pathway by which light information reaches the circadian system. However, this has been difficult to prove conclusively because the close proximity of the SCN to the optic chiasm in rodents has not made it possible to sever the RHT without destruction of the SCN. Indirect evidence of a major role for the RHT is the observation that rodents can entrain to a light/dark cycle when all known retinal inputs to the brain, except the RHT, have been destroyed. Nevertheless, disruption of the primary optic tract, leaving the RHT intact, can alter the entrainment pattern of the locomotor activity rhythm in hamsters7. The relative importance of the RHT and other retinal inputs to the brain for the entrainment of the circadian system by light still remains to be determined.

Through the use of recently developed neural anatomical tracing and staining techniques, new details about the morphology and the afferent and efferent connections of the SCN have emerged8. The SCN is a complex nucleus that has a number of recognizable subdivisions and within each division there is a heterogeneous population of neurones. Morphological studies of the SCN suggest that there is a great deal of intercellular communication within one nucleus as well as between the nuclei⁸⁻¹⁰. Inputs to the SCN arise from the retinae, ventral lateral geniculate nuclei and midbrain raphe nuclei, and a number of other inputs may exist¹⁰. Interestingly, the number of retinal ganglion cells projecting to the SCN is quite small and certain classes of ganglion cell are more likely to project to the SCN than others11. Relatively little is known about the efferent projections from the SCN but. in general, it appears they leave dorsally and caudally and many terminate among cells in various hypothalamic nuclei¹².

Direct evidence for the ability of the SCN to generate circadian rhythms has been supplied by Inouye and Kawamura¹³. They found clear evidence of circadian rhythmicity in neural activity in a variety of different brain regions when they recorded multiple unit activity with extracellular electrodes. When a Halasz knife was used to create a hypothalamic island containing the SCN, they found that circadian rhythmicity in spontaneous neural activity was abolished in all brain regions outside the island but persisted inside the island. This suggests that the SCN region is capable of generating circadian rhythms without input from elsewhere and that the rhythmicity in other brain regions is dependent upon input from the SCN. Circadian fluctuations in glucose consumption and protein synthesis 14,15

have also been observed in the SCN, although it is not known whether the rhythms are intrinsic to the SCN region itself.

A number of laboratories are attempting to record neural activity from the SCN in hypothalamic slices maintained in vitro. In a preliminary paper, Groos16 reported that single units from the rostral hypothalamus (including the SCN) maintained in vitro exhibited clear circadian rhythms in their firing rate and suggested that neural rhythms were intrinsic to the SCN.

Very few studies have examined the neurochemistry of circadian systems in mammals. Zatz17 has demonstrated that the infusion of carbachol, a cholinergic agonist, adjacent to the SCN could mimic the effects of light on the circadian rhythm of rat pineal N-acetyltransferase activity. These results suggest that acetylcholine may be involved in the photoentrainment of mammalian circadian systems and point out the potential usefulness of the neuropharmacological approach in determining the mechanisms by which circadian rhythms are entrained and selfgenerated.

Most of our understanding of the role of the SCN in the generation of circadian rhythms has been derived from investigations with small rodents, particularly rats and hamsters. However, recent studies involving lesions of the SCN region in lizards, birds and primates^{5,18} indicate that this region of the brain plays a central part in the circadian organization of many, if not all, vertebrate species.

Whether the SCN represent the master biological clock, or a major component of a complex circadian system, in mammals remains an unanswered question. However, whatever the precise role of the SCN in the generation of circadian rhythms turns out to be, one thing is clear; the SCN have provided neuroscientists with a starting point for the eventual elucidation of the neural basis of circadian rhythmicity in mammals.

Towards the numerical magnetosphere

from Martin Brown

THE SOLAR WIND is a tenuous stream of hot protons and electrons originating in the solar corona and flowing approximately radially outwards from the Sun into the Solar System at speeds of \sim 400 km s⁻¹. The Earth's dipolar magnetic field presents an obstacle to this flow and excludes it from a cavity known as the magnetosphere. Because the speed of the solar wind is greater than all hydromagnetic wave propagation speeds in the solar wind medium, the perturbing influence of the Earth on the flow reaches only to the order of ten Earth radii upstream, where a standing shock is found. Downstream from the Earth, the magnetosphere is extended in a tail to great distances.

The large quantity of data available from satellite and ground-based observations of electromagnetic fields, flow velocities and particle number densities around the Earth, both in the magnetosphere and the undisturbed solar wind, has encouraged theoretical research into magnetospheric phenomena. There is major interest in the calculation of the steady-state flow of the solar wind past the Earth and its dynamic response to changes in the solar wind. The complex geometry and the need to consider interactions between electric currents and electromagnetic fields make a complete analytical solution inaccessible, but two recent publications (Leboeuf et al. Geophys. Res. Lett. 8; 257, 1981; Lyon et al. Phys. Rev. Lett. 46; 1038, 1981) show that techniques of numerical simulation developed for research in aerodynamics and plasma physics may be very useful. Although the application of numerical methods to the global structure and behaviour of the magnetosphere is not a new idea, previous work suffered from lack of computing power and from inadequate simulation techniques which allowed only a simplified version of the problem to be considered: the shape of the magnetosphere was assumed and a flow around it calculated (Spreiter et al. Planet. Space Sci. 17; 233, 1969). Larger computers now make more ambitious models possible, and attempts to simulate the time-dependent behaviour of the magnetosphere in two and even three dimensions, treating fields and currents in a proper self-consistent way, are very fashionable.

Two-dimensional numerical models are quite common in many fields and produce respectable results, but three-dimensional simulations are still quite rare since they tax to the limit the memory size and speed of operation of the most powerful computers available. In spite of this, notable results have been achieved with three-dimensional computer codes, especially in the fields of controlled weather prediction,

thermonuclear fusion and aircraft design. The present restriction on memory size means that rather few mesh points can be used in each coordinate direction of the finite difference models. For example, in the simulation of Leboeuf et al. a mesh of size $32 \times 16 \times 8$ and spacing about one Earth radius was used, allowing only poor spatial resolution. A two-dimensional simulation (Lyon et al.) in the plane perpendicular to the path of the Earth's orbit around the Sun gives better resolution, but since the motion of particles and magnetic field lines around the sides of the Earth is important, a distorted picture emerges without resort to ad hoc procedures for attempting to include these effects.

Several recognizable magnetospheric features are reproduced in these models; density maxima are found at the nose and over the polar caps, and a low-density cavity exists behind the Earth's dipole field. The cross-sectional shape of the simulated magnetosphere also has similarities with that deduced from satellite measurements. Magnetic field line reconnection, an important process by which field lines can break and rejoin to neighbouring lines through resistive current flows, occurs in both models. Reconnection takes place in the nose of the magnetosphere where the interplanetary magnetic field (IMF), arriving with the solar wind, connects with the Earth's field, and in the long tail where the magnetic field configuration, directed away from the Earth in the southern half and towards the Earth in the northern half, is maintained by a perpendicular current sheet separating these regions. Field lines from the northern and southern halves near the current sheet can break and join each other leaving a neutral line downstream from the Earth. A so-called 'open' magnetosphere results from reconnection (Dungey Phys. Rev. Lett. 6; 47, 1961) since the IMF connects to the internal field of the magnetosphere, allowing entry of solar wind particles down the field lines. Although the general topology of these magnetic field line structures is reproduced in simulations, the rate of reconnection is much greater than it should be because of dissipative effects inherent in both methods which gives rise to 'numerical' diffusion of field lines. This causes the neutral line in the tail to be placed much nearer the Earth than it is in reality.

Some dynamic phenomena of interest appear in the models. Fluttering of the boundary of the simulated magnetosphere (Leboeuf et al.), which is also seen by spacecraft, appears to be the result of the well known Kelvin-Helmholtz instability. The two-dimensional code (Lyon et al.) attempts to model a geomagnetic substorm (a poorly understood, large-scale event in the magnetosphere powered by the solar wind) by switching on a southward-pointing IMF in the incoming solar wind. This causes rapid reconnection in the tail of

the model, the neutral line approaching the Earth and then receding in a way very similar to that seen in the magnetosphere and predicted by theory.

The numerical magnetosphere is, at present, a rather distant cousin of the real one, though they have many common

general features. These simulations can best be thought of as feasibility demonstrations; real advances will only come using much finer meshes on the next generation of large computers, and with the development of numerical schemes with less dissipation.

The evolution of cooperation

from Robert M. May

Most people are familiar with the paradox of 'The Prisoner's Dilemma', which provides an elegant metaphor for the problems of achieving mutual cooperation among members of a group. It has indeed been said (Grofman, in *Frontiers of Economics* University Publications, Virginia, 1975) that more than 2,000 papers have been written on the paradox and its philosophical implications.

In its basic form, the Prisoner's Dilemma involves two individuals, each of whom can choose either to cooperate or to defect in each of a series of discrete interactions. For these encounters, an illustrative pay-off matrix has the following character: if both players cooperate, each gains 3 units of whatever currency is at stake; if one cooperates and the other defects, the defector gains 5 units and the cooperator gets 0; if both defect, both gain 1 unit. It is apparent that, on any isolated encounter, the best strategy is to defect: if the opponent also defects, you score 1 rather than the 0 that you would have scored had you cooperated; if he cooperates, you score 5 rather than the 3 that cooperation would have gained for you. Thus, irrespective of the other player's choice, it pays to defect. But, if both players defect, both score 1 unit rather than the 3 units they could both have scored had they cooperated. Hence the

Clearly, the players' strategic decisions will depend on the likelihood of future encounters. If the individuals know they are destined never to meet again, defection is the only rational choice. By extension, if the total number of interactions is precisely known in advance, defection seems to remain the unbeatable strategy (defection is optimal on the last encounter, and therefore also on the next-to-last, and so on, back to the first).

However, if the series of encounters is to stretch indefinitely into the future, or, more generally and more realistically, if there is always a finite probability, w, that after the current interaction the two protagonists will meet again, the strategic choices become more complex.

Robert M. May is Class of 1877 Professor of Zoology at Princeton University.

Smale (Econometrica 48; 1617, 1980) has recently brought the formal apparatus of the theory of dynamical systems to bear on the problem, in the limiting case when there is no finite horizon and no discounting of the future. In these models "There is always a tomorrow in our plans, and it is as important as today. . . . There is a history, a beginning of history, but no end". On the assumption that decisions may be based on some kind of summary or average of past outcomes, Smale shows that there is a class of 'good strategies' that are optimal and stable, corresponding to 'Nash equilibrium points'. These good strategies are essentially cooperative ones. Although Smale's analysis is formal and abstract, it clearly demonstrates that cooperative strategies can arise, provided some plausible general conditions are met.

A more empirical approach to the problem of finding a 'best' strategy is reported by Axelrod and Hamilton (Science 211; 1390, 1980), in a paper whose title I have stolen for this News and Views article. In two computer tournaments, Axelrod solicited strategies for playing the Prisoner's Dilemma game (with the specific pay-off matrix defined above) from game theorists in economics, sociology, political science, mathematics, physics and evolutionary biology. The first tournament involved a total of 15 entries, which were paired against each other in a round robin tournament, with each contest lasting 200 moves. The 15 strategies varied from the very elaborate ("An example is one which on each move models the behaviour of the other player as a Markov process, and then uses a Bayesian inference to select what seems the best choice for the long run"), to one in which each choice was totally random. The winning strategy was a simple one entered by Anatol Rapoport (of the Institute for Advanced Study at Vienna). Called TIT FOR TAT, it cooperated on the first move, and thereafter did whatever its opponent did on the previous move. Axelrod's second, larger tournament had 62 entries from six countries, and the pairwise contests lasted an average of about 200 moves (specifically, there was a probability w = 0.99654 that any given move would not be the last). Again, Rapoport's TIT FOR

TAT emerged clearly triumphant.

In retrospect the success of TIT FOR TAT can be attributed to three features: it was never the first to defect, it immediately retaliated when provoked, and it was forgiving after just one act of retaliation.

TIT FOR TAT's emergence as the 'best' strategy from the maelstrom of contenders in Axelrod's tournaments depends explicitly on the protagonists meeting again and again. Pursuing this aspect of the problem in an analytical way, Axelrod and Hamilton show that (with the pay-off matrix defined above) TIT FOR TAT will always win provided the probability, w, for a given pair of players to meet again exceeds 2/3. More generally, if the reward for mutual cooperation is R units, for mutual defection is P units, and for cooperation-defection is T to the defector and S to the cooperator, then the strategy of TIT FOR TAT will dominate all others provided that the probability, w, of a subsequent encounter exceeds

$$(T-R)/(R-S)$$

Notice that, in this general case, we must have T > R > P > S for the Prisoner's Dilemma to exist; also we require that R > (S + T)/2 (otherwise alternation of cooperation and defection is superior to sustained mutual cooperation).

These heuristic and theoretical studies of the Prisoner's Dilemma are of interest in their own right. Axelrod and Hamilton, however, go further to make a convincing case that this model sheds light on the way cooperation may evolve by darwinian selection in the natural world, among groups of individuals who are not necessarily closely related.

Axelrod and Hamilton emphasize that a formal theory for the evolution of cooperation needs to answer three questions. First, how can a cooperative strategy get an initial foothold in an environment which is predominately noncooperative? Second, what type of strategy can thrive in a varied environment composed of other individuals using a wide diversity of more or of less sophisticated strategies? Third, "under what conditions can such a strategy, once fully established, resist invasion by mutant strategies (such as 'cheating' by pure defectors)?" The studies of TIT FOR TAT answer these questions about initial viability, robustness and stability. Provided the probability that interaction between two individuals will continue is sufficiently great, cooperation based on reciprocity can indeed get started in an asocial world, can flourish in a variegated environment and can defend itself once fully established.

In sketching tentative biological applications of their ideas, Axelrod and Hamilton note that there are two main requirements for cooperation to evolve by this broad route. The first is that "an individual must not be able to get away with defecting without the other individuals being able to retaliate effectively.

The response requires that the defecting individual not be lost in an anonymous sea of others. Higher organisms avoid this problem by their well developed ablity to recognize many different individuals of their species, but lower organisms must rely on mechanisms that drastically limit the number of different individuals or colonies with which they can interact effectively". The second requirement is that the probability w for the same two individuals to meet again must be sufficiently high.

One way to help keep the interactants together is to use some fixed place of meeting. Thus aquatic cleaner mutualisms (in which a small fish or a crustacean removes and eats ectoparasites from the body, or even the inside of the mouth, of a larger fish which is its potential predator) "occur in coastal and reef situations where animals live in fixed home ranges or territories"; they seem to be unknown in the free-mixing circumstances of the open sea. Pursuing this line, the authors also argue that ant colonies participate in many cooperative mutualisms, whereas honeybee colonies — which are much less permanent in place of abode - have no known cooperative symbionts but many exploitative parasites.

An important simplification in the work of Axelrod and Hamilton, and in Axelrod's computer tournaments, is that all pay-offs are counted equally. The future is not discounted. In many

biological applications, however, future gains (measured in terms of reproductive effort or other coinage related to darwinian 'fitness') may be worth much less than current gains. One offspring in the hand can literally be worth two in the future. I think Axelrod and Hamilton's analysis can be widened to include such discounting of future gains, at least in simple cases, by formally redefining the probability of future encounters, w, to include an appropriate discount factor. If this is so, it adds a further requirement that must be satisfied before cooperation can evolve: not only must there be a sufficiently high probability that any two protagonists will encounter each other again, but also the gains from such future encounters must not be too heavily discounted. This consideration is an additional restriction on the biological circumstances under which cooperation may be able to evolve along the lines envisioned by Axelrod and Hamilton.

In a survey of organisms ranging from bacteria to primates, Axelrod and Hamilton indicate many examples where aspects of territoriality, mating systems or disease may be related to the evolution of cooperation. Intriguing though these speculations are, I think the real importance of their paper is in providing a rigorous, formal example of a mechanism whereby cooperation based on reciprocity may evolve.

New twists to DNA and DNAcarcinogen interactions

from Stephen Neidle

THE discovery of left-handed DNA structures (the Z forms) has undoubtedly provided a major impetus to the reawakening of interest both in nucleic acid structure generally and in wider questions of nucleic acid recognition. Such recognition, whether by proteins (see D.R. Davies News and Views 290; 736, 1981), or by smaller molecules such as drugs, mutagens and carcinogens, must to some extent be specific to the sequence of the nucleic acid residues involved. It is now apparent from the crystal structure analysis1 of the dodecanucleotide DNA fragment d(CGCGAATTCGCG) that subtle, yet distinctive, sequence-dependent structural features occur at differing points on a classical right-handed B-DNA-type double-helical nucleic acid. These are seen

sequence which has the potential of existing in the very different Z-DNA left-handed form. It is thus in principle interesting to ask whether such aberrant regions of structure are involved in recognition processes.

A central question concerns the con-

in an extreme form in an alternating dG-dC

A central question concerns the coexistence of left- and right-handed helices within the same trait of DNA. Recently, it has been reported that oligomeric (dG-dC) fragments of known size have been successfully inserted into DNA restriction fragments2. Both circular dichroism and phosphorus (31P) NMR measurements showed that these alternating sequences behaved in a manner typical of the $B \rightarrow Z$ transition induced by increases in salt concentration. Since the non-alternating sequences in the fragments studied did not show such behaviour, it is clear that both forms of DNA can co-exist, with a roughly eleven-base pair interface between them. The visualisation of this intermediate area

Stephen Neidle is in the Cancer Research Campaign Biomolecular Structure Research Group, at the Department of Biophysics, King's College London. will surely provide fertile ground for the model-builders, at least until relevant crystal structures are obtained. Even though the result implies that a considerable length of (dG-dC) oligomer is required for full Z character to be shown in between these interfacial regions, it is not unreasonable to suppose that rather shorter (dG-dC) traits will have some abnormal structural character.

The salt-induced conformational transition of DNA (B - Z) is the basis of all experimental probes of left-handed DNA in solution. However, it remains true that until recently, it has been no more than a strong presumption (albeit a logical one) that the high-salt form in solution does indeed correspond to the left-handed structures observed in the crystalline solid state. Evidence is now accumulating that this assumption is a valid one. Thus, Sarma and his associates3 have shown that the observed proton NMR chemical shift data for high-salt poly(dG-dC). poly(dG-dC) corresponds very well with the spectral data calculated theoretically from a Z-DNA helical structure, and not at all with that from B-DNA. Furthermore, it is evident that this close agreement almost certainly excludes other more recherché DNA structures, at least in this context. Interesting structural questions have been posed by the observation4 that the alternating copolymer, when fully methylated at the cytosine 5 position, undergoes a B-Z transition at a roughly physiological salt concentration which is much less than that required for the transition in the unmethylated polymer. Since it has often been suggested that C5 methylation in eukaryotes is related to control of gene expression, it is indeed tempting to speculate that here, at last, may be a role for Z-DNA. Indeed one keenly awaits firm evidence that any biological function actually does involve a switch of DNA helicity from B→Z. The recent production of antibodies specific for the Z form⁵ may well prove to be a powerful tool for providing such data.

It was apparent soon after the discovery of Z-DNA that certain atoms, such as the C-8 of guanine residues, are rather more exposed than in B-DNA6. The C-8 site is favoured in binding of the tricyclic aromatic hydrocarbon derivative acetylaminofluorene (AFF), a muchstudied hepatic carcinogen. In view of this, and the knowledge that at least some mutational hot-spots (for example in

'Ames-test' histidine genes of Salmonella strains) contain clusters of alternating (dGdC) residues, there has recently been much interest in the possibility that Z-DNA is involved in carcinogenic processes.

35445

Interaction of poly(dG-dC). poly(dGdC) with the active species N-acetoxy-AAF results in random modification7-9 of the polynucleotide, which then shows Z-like character even at low salt concentrations. No helix disruption seems to have occurred as the polynucleotide is not susceptible to S, nuclease which attacks single-stranded regions. The physical model that emerges is of AAF attaching to guanine residues which then for purely steric reasons have to be in the syn conformation of Z-DNA itself. On the other hand, with nonalternating (essentially random) sequences AAF binding involves some local destabilisation of the double helix, such as is suggested by a base displacement model9. This has the syn guanine residue no longer paired but swung out and displaced from the double helix. One suspects that these two types of AAF-binding models are actually closely related in structural terms. It will be of some interest to see how they differ biologically, such as in their susceptibility to excision repair.

Diphtheria toxin: which route into the cell?

from Simon van Heyningen

A single molecule of diphtheria toxin can kill a eukaryotic cell. Several other bacterial protein toxins also have comparable activity and all are large molecules which have to penetrate the cell membrane before they can act. Diphtheria toxin was the first of these to be understood, at least in outline, but several important details have only recently been published.

Diphtheria toxin (molecular weight 60,000) is made up of two polypeptide chains, fragment A (21,000) and fragment B (39,000), linked by a disulphide bond. The toxin first binds to cells through the B fragment. This leads to the entry into the cell of fragment A - which then folds to an active conformation, and catalyses a reaction in which the ADP-ribose of NAD is transferred to elongating factor 2 (EF2), an essential protein component of ribosomal protein synthesis. Since ADPribosylated EF2 is inactive, protein synthesis stops and the cell dies. It is because fragment A is an enzyme that the toxin is so active.

Fragment A is highly specific. Its only significant substrate is a single amino acid residue in EF2 whose structure has recently been determined by NMR1. It is a complex derivative of histidine named 'diphthamide', 2-(3-carboxyamido-3-[trimethylammoniol propyl)histidine. The specificity of the toxin is not, however, just for diphthamide, but for something more complicated: peptides containing diphthamide isolated from tryptic digests of EF2 are not ADP-ribosylated.

Since the toxin ADP-ribosylates the EF2 of all eukaryotes (and even of the archaebacteria), diphthamide must be highly conserved. The amino acid sequence around it also shows little species variation. It is hard to believe that so complicated a modification has evolved to provide a substrate for diphtheria toxin, so one might expect diphthamide to be required for the action of EF2. Surprisingly, however, mutants that lack diphthamide (and are insensitive to toxin) show no defect in protein synthesis. These mutants can be divided into three complementation groups, in agreement with the number of enzymic modifications which the structure of diphthamide suggests would be needed to make it from histidine. Diphthamide is presumably also the substrate for ADPribosylation by the toxin of Pseudomonas aeruginosa, which works in a very similar way, but not for cholera or E. coli toxins which are less specific and ADP-ribosylate different proteins.

Before fragment A can have its effect on EF2 it first has to pass into the cell. Entry begins with the binding of fragment B to a receptor on the outside of the cell membrane. The nature of this receptor was unknown until recently (although it had been mapped on the human chromosome), but is has now been identified as a glycoprotein that can be isolated from guinea-pig cells by immunoprecipitation². It is not a true receptor in the endocrinological sense, since binding to it does not in itself have any effect. Rather, it is a prerequisite for entry that the toxin birds firmly to the cell. Quite different ways of doing this are effective; derivatives of fragment A with other cell-surface ligands such as antibodies or even subunit B of cholera toxin can still enter the cell.

Once the toxin is bound there are two different ways in which the A fragment could enter the cell. It could cross the

membrane directly (either by itself or with a carrier), or it could be endocytosed, in which case the problem of crossing the membrane into the cytosol would still remain. For this and other reasons, endocytosis has not been a favoured hypothesis, but some new experiments have made it seem much more likely³.

Uptake of toxin is greatly increased at low pH. When cells are exposed to toxin at pH 4.5 for ten minutes, the rate of decrease in protein synthesis is the same as it would have been using a thousand times as much toxin at neutral pH. As the pH is low in the lysosomes, the results immediately suggest that that is where toxin might normally enter the cell. There is other evidence that this is what happens. When the pH inside the lysosomes is increased by incubating the cells with ammonium chloride, the toxin is very much less active (although its binding to the cell surface is not decreased). However, this protective effect of ammonium chloride is abolished if the cells are exposed to low pH for even as little as 20 seconds. Experiments using antisera suggest that, at neutral pH, toxin is trapped in intracellular vesicles, but, at low pH, it can penetrate the membrane directly; lysosomes are no longer involved and so ammonium chloride has no effect.

What may normally happen is that the toxin is taken up by endocytosis into intracellular vesicles which then fuse with lysosomes. Most of the toxin will be destroyed by the lysosomal enzymes, but at the low pH in the lysosomes, a few molecules of fragment A will escape into the cytoplasm.

How does fragment A penetrate membranes at low pH? Recent experiments using artificial lipid bilayers may provide a clue4. Diphtheria toxin and a mutant (crm 45) that lacks the receptor-binding region of fragment B can bind to these layers and form transmembrane channels through them. These channels are formed best when one side of the membrane is at low pH and the other is neutral, and their width (perhaps about 18 Å diameter though there is some disagreement) is probably large enough for fragment A to pass through provided it unfolds to a fully extended form. Fragment A is a very stable protein which could easily refold to a native conformation afterwards.

The formation of these channels probably involves more than one molecule of fragment B transversing the membrane. Fragment B is well able to do this: it has a

hydrophobic domain that could dissolve in the core of the membrane lipids, and a hydrophilic domain that could interact with the polar head groups⁵.

It seems unlikely that the mechanisms used by bacterial toxins for entering cells

and affecting their metabolism are unique. Rather, they may also be used in other, as yet unidentified, ways. Study of these curious proteins should help the understanding of the normal properties of cells.

The actin-myosin interface

from Howard White

UNDERSTANDING the molecular mechanism of muscle contraction will almost certainly require a detailed knowledge of the structure of, and the interaction between, the primary contractile proteins, actin and myosin. A simple model in which each myosin-S1 binds to a site completely contained with a single actin subunit has been generally assumed from the binding stoichiometry of one myosin-S1 per actin subunit. The observation made several years ago by Chantler and Gratzer (Biochemistry, 15, 2219; 1976) that myosin-S1 binds to monomeric actin covantly bound to sepharose strengthened the case for a simple one-to-one interaction between each myosin head and actin filament subunit.

In this issue of *Nature* (p.301) Mornet *et al.* report that a water soluble carbodiimide crosslinks the 95K dalton heavy chain of myosin-S1 to two actin subunits and conclude, that the binding site for each myosin-S1 to filamentous actin spans two actin subunits or is at least close enough to form zero-length crosslinks with two actin subunits. Although crosslinking experiments of this type have a rather perilous history, the authors have devised an extensive series of controls that considerably strengthen their argument.

First, the crosslinking reaction is quite specific. Actin activated with carbodiimide is crosslinked to myosin-S1 but myosin-S1 activated with carbodiimide is not crosslinked to actin. The crosslinking reaction is prevented by either pyrophosphate or MgATP, which specifically dissociates myosin-S1 from actin. Second, the composition of the crosslinked species, two actin subunits and one myosin-S1 heavy chain, initially suggested by a molecular weight of 180K dalton on SDS gels was verified by a molar ratio of two 3 H-actin to ¹⁴C-S1 in the crosslinked polypeptide. Third, the possibility that S1 binding to actin enabled intermolecular crosslinks to be formed between actin subunits was eliminated by the following experiments. Trypsin specifically cleaves the heavy chain of myosin-S1 bound to f-actin into two peptides of 75K and 22K daltons; cleavage of carbodiimide crosslinked actomyosin-S1 produces two peptides with molecular weight of 120K and 64K daltons. The proteolytic fragments of the

crosslinked actomyosin-S1 were identified as 22K (S1)-actin and 75K (S1)-actin by specific fluorescent labeling of the actin and myosin-S1 before crosslinking and cleavage.

Hence, two different regions of the myosin-S1 heavy chain appear to be cross-linked to separate actin subunits. The authors propose a model in which the myosin-S1 binds to a site comprising two actin subunits on opposite strands of the actin helix. However, their data and recent three-dimensional reconstructions obtained from electron micrographs of negatively stained actomysin-S1 filaments (Taylor and Amos J. molec. Biol. 147, 297; 1981) are equally compatible with the myosin-S1 being bound to two actin subunits on the same strand of the actin filament.

The enzymatic properties of the crosslinked actomyosin may provide a new tool to help unravel the increasingly complex mechanism of actomyosin ATP hydrolysis. Crosslinked actomyosin-S1 hyrolyzes MgATP at a rate comparable to the rate of hydrolysis by actomyosin-S1 in solution extrapolated to infinite actin concentration. There is, however, one notable difference — the large dependence of rate upon ionic strength that is so characteristic of actomyosin-S1 in solution (primarily due to the ionic strength dependence of the equilibrium of $M \cdot ADP \cdot P_i + actin \ge acto \cdot M \cdot ADP \cdot P_i$ which precedes the rate-limiting step) is absent. Crosslinked actomyosin-S1 thus appears to provide a covalent model for the so-called non-dissociating pathway of actomyosin ATP hydrolysis that could previously be observed only at a very low, non-physiological ionic strengths.

One may well ask how all of this fits the notion of rotation of the myosin heads bound to actin — the postulated work-producing step of most of the popular models of contraction today. The molecular basis of muscle contraction is indeed far from being solved and continues to provide both the structuralists and biochemists with more riddles to decipher.

Magma chamber profiles from the Bay of Islands ophiolite complex

J. F. Casey*‡ & J. A. Karson†

*Department of Geological Sciences, State University of New York at Albany, Albany, New York 12222, USA †Department of Geology and Geophysics, Woods Hole Oceanographic Institution, Woods Hole, Massachusetts 02543, USA

Models of the oceanic lithosphere derived from constraints imposed by the geology of ophiolite complexes require a magma chamber to produce the cumulate and other plutonic portions of the oceanic crust and upper mantle. Evidence from the Bay of Islands ophiolite complex indicates that layered plutonic rocks have not formed solely due to differential crystal settling to the horizontal floor of a magma chamber, but have formed largely by heterogeneous nucleation and in situ crystallization along gently inclined as well as steeply inclined bounding surfaces of a large magma reservoir. Coherent, well defined and systematically oriented, large-scale, arcuate patterns described by mesoscopic igneous layering have been identified in the plutonic sections of two ophiolite massifs in the Bay of Islands complex. These layering patterns seem to outline the shape of a large, continuously evolving, steady-state magma chamber that extended along a ridge axis and ended at a transform fault intersection.

EVIDENCE from marine geology, geophysics and theoretical considerations suggests that steady-state magma chambers may exist beneath fast-spreading accreting plate boundaries 1-6 while only small ephemeral chambers may occur along slow-spreading plate boundaries⁷. Previous models for the evolution of the oceanic crust and upper mantle have been built around the concept of a steady-state chamber and generalized observations from ophiolite complexes^{6,8-11}. Ophiolite complexes provide cross-sectional views of large-scale, metamorphic-plutonicvolcanic layered sequences widely believed to be on-land exposures of ancient oceanic lithosphere 11,12. There is general agreement that volcanic rocks and underlying sheeted diabase dykes are formed by continuous crustal extension and magmatism at an oceanic spreading centre. The evolution of the underlying stratiform plutonic assemblage, however, has been modelled in several different ways. All models must deal with the problem of producing a subhorizontally layered assemblage from a continuously widening subvertical crack. All previous steady-state models assume the formation of cumulates occurs only along subhorizontal surfaces, but this requires extremely large magma chambers^{9,11} uhless tectonic rotations occur⁸. Most interpretations of ophiolites suggest that cumulate layering should be restored to a subhorizontal orientation parallel to the large-scale stratiform structure of the complex 11,13,14. Evidence from the plutonic sections of the Bay of Islands ophiolite complex, however, indicates that 'cumulates' have formed along steeply inclined magma chamber walls and that the final geometry of the fine-scale igneous layering is much more complex than that assumed in most previous models or than is apparent from reconstructions of dismembered ophiolites.

Bay of Islands ophiolite complex

The Bay of Islands ophilite complex (Fig. 1) is located along the west coast of the island of Newfoundland, Canada. The ophiloite is exposed in four large massifs (each ~ 20 km across) which are considered to be the dissected remnants of a once continuous allochthonous sheet of early Ordovician oceanic crust and upper mantle. The tectonic setting and rationale for the interpretation of the complex as oceanic lithosphere are discussed elsewhere 15-20. The large-scale stratiform structure of the ophiloite complex (Fig. 2) includes (from base to top): metamorphic tectonic periodotite, ultramafic and mafic plutonic rocks,

sheeted diabase dykes, and basaltic volcanic rocks. The Bay of Islands ophiolite clearly conforms to the current working definition of an ophilite complex¹¹ and includes wide outcrop areas suitable for detailed studies. Although the uppermost units have in some places been removed by erosion, and some

sections are structurally dismembered, uninterrupted sections interpreted as exposures of former upper mantle to sea floor, are well preserved.

The Bay of Islands complex may be divided into two petrogenetically distinct components (Fig. 2), a residual upper mantle assemblage depleted by subcrustal partial fusion and extraction of basaltic liquids^{8,21,22}, and a 'magmatic' component, the assemblage derived by differentiation of those basaltic extracts. The magmatic component can be divided into two large-scale structural assemblages²³. One is an upper intrusive-extrusive carapace of mafic volcanics and sheeted diabase dykes interpreted as the continuously extended and rapidly cooled lid of a magma chamber. The second is a plutonic group believed to have formed by fractionation of basaltic melt in a crustal-level magma chamber. This group includes (from base to top): (1) layered ultramafic cumulates, mainly dunite, wehrlite, clinopyroxenite and chromitite; (2) interlayered ultramafic and gabbroic cumulates (the transition zone), mainly dunite, wehrlite, troctolite, olivine-gabbro and anorthosite; (3) layered gabbroic cumulates, mainly troctolite, olivine-gabbro and gabbro; and (4) isotropic gabbroic rocks, mainly gabbro and metagabbro. This type of plutonic association has been observed in many ophiolite complexes and, by analogy to continental stratiform intrusive bodies, is interpreted in terms of magma chamber processes 11.3 We believe that the internal structure of the plutonic group of the magmatic component can provide some useful constraints on the dimensions and shape of the magma chamber(s) from which the complex formed.

It is assumed in reconstructing the massifs, which are now folded on a large scale, that major, lithostratigraphic-unit contacts had a subhorizontal orientation before obduction and that the mean orientation of diabase dykes was parallel or subparallel with the ridge axial plane at the time of formation. In general, two distinct types of crustal cross-sections are preserved in surface exposures of the complex. One type is reconstructed

as an approximately vertical section through the Bay of Islands complex and is oriented parallel to a spreading flow line (that is, normal to the palaeo-spreading centre and parallel to fracture zones). This type of section is exposed in map view of the northern three massifs (Figs 1 and 3a) due to tilting of major lithostratigraphic units about obduction-related, clinal fold axes oriented approximately parallel to the spreading direction²⁵. The second type of section is preserved in surface exposures of the southernmost massif, the Lewis Hills (Figs 1 and 3b). The Lewis Hills section exposes the intersection of the Bay of Islands complex with a subvertical zone containing a highly deformed and metamorphosed ophiolitic assemblage, the coastal complex, which is interpreted as oceanic crust and upper mantle with a history of transform fault tectonics predating its juxtaposition with the Bay of Islands complex^{20,26}. The outcrop pattern of the Lewis Hills massif is controlled by a large scale, obduction-related syncline; its axis plunging gently to the northnorthwest approximately parallel with the inferred spreading direction and the trend of the coastal complex. The western part of the massif lies in the core of this syncline and exposes the subvertical, highly-deformed coastal complex. The eastern side of the massif is tilted to the west and exposes the deeper structural levels of the plutonic section and the upper levels of the harzburgite section of the Bay of Islands complex.

Internal structure of the plutonic group

Contrary to assumptions commonly made in the reconstruction of dismembered ophiolite sections, the mesoscopic-scale cumulate layering is generally not parallel to the contacts between the large-scale lithologic units as first noted by Dewey and Kidd⁸. Broad arcuate patterns, defined by cumulate layering oriented up to 90° oblique to lithologic unit contacts, are observed within the plutonic group. Although in detail these arcuate patterns

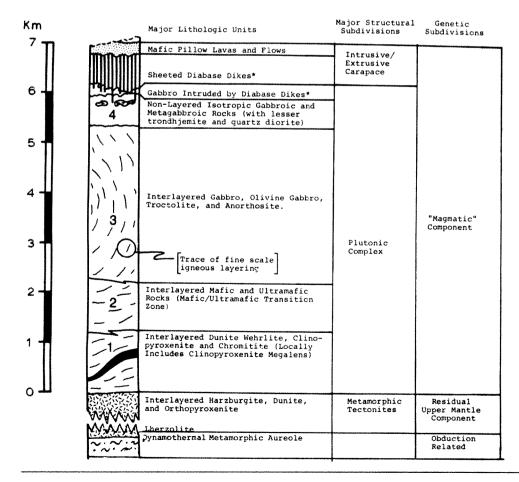

Fig. 2 Generalized columnar section through the Bay of Islands ophiolite complex and interpretations of major lithologic units. The magmatic component is to scale; the residual component is condensed (actual thickness approaches 4-5 km).

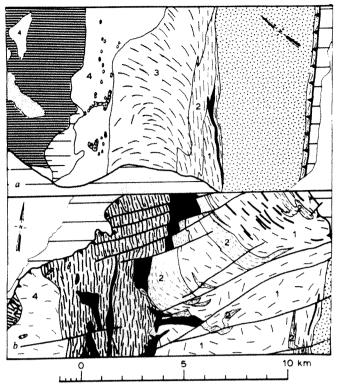

Fig. 3 Geological sketch maps of two areas in the Bay of Islands ophiolite complex (see Fig. 1). a, Southern half of the North Arm Mountain massif. Shading as in Figs 1 and 2, ruled lines on the diabase dyke units are oriented in the approximate direction of the mean dyke trend. b, Central part of the Lewis Hills massif. Light grey shading and bold squiggles indicates highly deformed rocks of the coastal complex including highly strained ultramafics, mertagabbros, amphibolites, and granulites; dark grey shading indicates intrusive periodotite bodies of the coastal complex; bold dashed lines are chromitite megalens units. Both maps are oriented with the mean trend of diabase dykes (the palaeo-ridge axis trend) parallel with the longer edges of each map.

appear to be quite irregular, the large-scale relationships are clear. In two of the massifs, North Arm Mountain and the Lewis Hills (Fig. 3), detailed mapping has revealed especially welldefined arcuate structures described by fine-scale igneous layering. The patterns identified in these two massifs, however, have very different geometric relationships with respect to the inferred spreading direction during formation of the complex. (The textural terminology and classifications systems developed for rocks believed to have originated by crystal settling^{27,28} can be applied to many coarse-grained plutonic rocks regardless of origin. We do not interpret layered plutonic rocks of the Bay of Islands ophiolite as cumulates in the genetic sense, but use the terms cumulate, cumulus, primocryst, intercumulus and postcumulus because they are descriptive regardless of the rocks origin and because a satisfactory, non-genetic terminology is not well developed. For further discussions see refs 29, 30.)

The southern half of the North Arm Mountain massif²⁵ (Fig. 3a) exhibits the best defined example of this arcuate structure in the Bay of Islands complex. We emphasize, however, that similar discordant relationships between cumulate layering and unit contacts have been mapped in all of the other massifs. In the North Arm Mountain massif a nearly complete ophiolite sequence is preserved. The present-day erosional surface which truncates the sequence is nearly parallel to the inferred seafloor spreading flow lines, that is, normal to the mean trend of diabase dykes in the sheeted dyke unit. Fine-scale igneous (cumulate) layering attitudes within the plutonic group change gradually and continuously upward from subparallel to the major lithologic unit contacts (that is palaeohorizontal planes) in the basal ultramafic and transition zone units to orientations highly oblique to these contacts in the gabbroic units. At the upper

contact of the layered gabbroic rocks (Unit 3, Fig. 3a), layering attitudes are $\sim 90^{\circ}$ or even apparently overturned with respect to the major lithologic unit contacts. In a reconstructed section the discordant fine-scale igneous layering consistently strikes subparallel to the sheeted dyke direction while defining broad arcuate patterns as depicted in Figs 3 and 4. The axis of this arc or bend in the layering lies approximately in the plane of the major lithologic unit contacts and also in the plane of the mean dyke orientations indicating that, as exposed, the pattern essentially defines a cross-section of a half cylinder whose long axis originally lay in a subhorizontal orientation within the ridge axial plane. The convex side of the arc points towards the spreading direction which is inferred from one-way chilling statistics from the sheeted dyke unit and the sense of shear deduced along the coastal complex transform 20,26 .

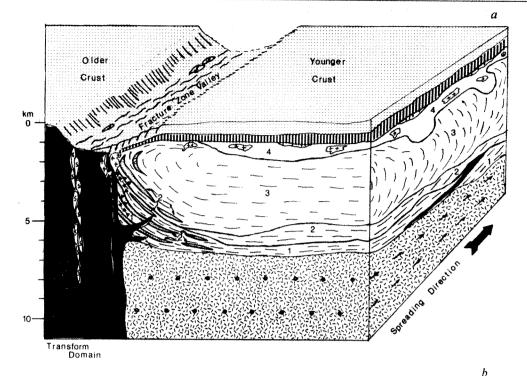

A single clinopyroxenite-rich 'megalens' paralleling fine-scale layering occurs within the ultramafic cumulates on North Arm Mountain. This megalens varies in thickness from 0 to 300 m (Fig. 3a) and consists of aggregates of small lenses or layers of dominantly clinopyroxenite, with lesser amounts of interlayered dunite, wehrlite and chromitite. This megalens can be traced laterally for over 4.0 km as it cuts obliquely across the ultramafic cumulate section. Where the megalens intersects the lower contact of the transition zone, clinopyroxenites become interlayered with gabbroic rocks. These gabbroic layers increase in abundance with height in the transition zone at the expense of clinopyroxenite layers until the megalens cannot be distinguished.

An important relationship within the plutonic group concerns the relative orientations of fine-scale igneous layering, megalenses, the contacts between major lithologic subdivisions of the plutonic assemblage, and the direction of cryptic chemical variations. In continental stratiform intrusions, to a first approximation, fine-scale igneous layering is controlled by and lies parallel to the various major rock units. It also remains orthogonal to the direction of cryptic chemical variations. Fine-scale layering and megalenses in the Bay of Islands complex plutonic group, however, consistently maintain an oblique relationship to the contacts beween the major lithologically defined subdivisions of the plutonic group and in some cases have trends parallel with the direction of cryptic chemical variations²².

Similar, but as yet less well-defined arcuate structures occur elsewhere in the Bay of Islands complex on the Blow-Me-Down Mountain and Table Mountain massifs where highly oblique layering relationships are also present. In the Lewis Hills massif^{26,32}, a different, but well-defined arcuate structure is present (Fig. 3b). Cumulate layering and (layered cyclic) megalens units up to 1.0 km thick are mutually parallel throughout the plutonic group. In the eastern half of the massif these features lie subparallel to the basal contact of the magmatic suite along that contact and in the central part of the massif layering is subhorizontal. To the west, however, fine-scale igneous layers vary continuously in orientation through approximately 90° approaching subvertical adjacent to the coastal complex. These layers commonly include local concentrations of angular detached blocks of layered gabbro. This geometry and these intrusive relationships suggests lapping of the plutonic group against the subvertical contact with high-grade metamorphic rocks of the coastal complex. The structure preserved in the Lewis Hills massif probably formed as relatively young crust of the Bay of Islands complex was accreted to older deformed crust of the coastal complex at a ridge/transform intersection^{20,26}. The axis of the large-scale arcuate structure defined in this area lies parallel to the inferred trend of the fracture zone and normal to the attitudes of undeformed diabase dykes in the massif (that is, approximately perpendicular to the axis defined for the northern massifs).

Interpretation of the internal structure of the plutonic group

Although the large-scale lithologic unit thicknesses and details of the internal structure of the plutonic group vary considerably

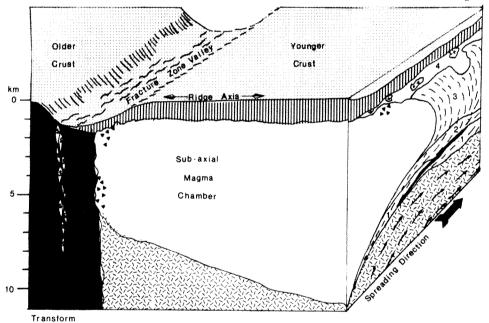

Fig. 4 a, Block diagram summarizing the reconstructed preobduction, post-accretion geology geometrical relationships within the Bay of Islands and coastal complexes. The front face of the block diagram is oriented perpendicular to the spreading direction and crosses an inactive transform domain (the coastal complex). The other face of the diagram is oriented parallel to the spreading direction. b, Block diagram depicting a schematic model for the formation of the geology depicted in a. Orientation of diagram is similar, except that the front face is coplanar with the ridge axial plane and it crosses the transform domain at the point at which it becomes inactive. The arcuate geometry of the fine-scale igneous layering and megalenses is the product of heterogeneous nucleation, in situ crystallization and layer formation along the bounding surfaces of the steady-state magma chamber. Shading as in Figs. 1-3. S. serpentinite: ▲ xenoliths; small arrows, flow paths in the upper mantle.

across the Bay of Islands complex²³, these differences seem to represent variations on a fairly simple theme. In the two types of arcuate structures described above, mesoscopic and sometimes even larger-scale cumulate layering are clearly not parallel to the contacts between the large-scale lithologic units. By analogy with the inferred horizontally-layered seismic structure of contemporary oceanic crust these contacts probably originated in a subhorizontal orientation. Whereas the deepest structural levels of the Bay of Islands plutonic group show signs of extensive subsolidus deformation, we emphasize that the bulk of this group has not been penetratively deformed^{23,25,26}. Therefore, we believe that the first-order geometry of layering as described above must be the result of igneous processes because we have accounted for all obduction or post-obduction structures in the reconstructions.

Domain

Numerous studies of igneous plutons with cumulate layering indicate that cumulate textures and layering commonly can form along subvertical walls of magma chambers as well as sub-

horizontal floors ^{29,30,33-36}. Integrated field and theoretical studies of cumulate rocks suggest that crystals nucleate and grow mainly along the margins of large magma chambers rather than homogeneously throughout the magma followed by vertical settling²⁹. Thus, cumulate layering may mimic the shape of the walls of such magma chambers as, we believe, is the case in the Bay of Islands complex. Any model for the origin of the igneous layering requires formation along the magma/wall (or floor) interface and therefore these layers must define isochrons. The fact these igneous layers as well as megalens units generally cut across major lithologic unit contacts and sometimes parallel the general direction of cryptic chemical variation within the plutonic group of the Bay of Islands complex implies pronounced and probably systematic physical and/or chemical heterogeneities along the bounding surface of the magma chamber.

Certain detailed aspects of the plutonic rocks, which are pertinent to the discussion of the origin of the fine-scale igneous layering in the Bay of Islands complex, also support the conten-

tion made above on the grounds of layer discordancy that much of the plutonic section formed by in situ crystallization processes at the bounding surface of the magma chamber. Fine-scale igneous layering in the plutonic section generally ranges in thickness from less than a centimetre to a few metres. Two types of layering are dominant. The first type, designated 'uniform layering', is characterized by uniform modal proportions and physical and textural properties. The second type, designated 'stratified layering', is characterized by size and/or modal stratification. The most common examples of stratified layers in the complex are those exhibiting modal stratification, but lacking size stratification. Size-stratified layers are present only locally and layers exhibiting both size and modal stratification are rare. Many of the stratified layers exhibit reversed stratification and some single layers exhibit both normal and reversed stratification. Where studied in detail²⁵, however, most layers (>80%) in the Bay of Islands plutonic sections are uniform in character. Consequently, the dominant sequence of layer types consists of successive uniform layers with a general lack or total absence of interlayered stratified layers. These sequences of solely uniform fine-scale igneous layers cannot be explained by the 'intermittent current hypothesis' proposed by Wager and others^{27,37} which is a model of layer formation by differential crystal settling in conditions of continuous crystallization within a magma chamber, because such a model demands that layer sequences be characterized by either alternating uniform and stratified layers, or successive stratified layers. Because of the abundance of sequences exhibiting successive uniform layers without intervening stratified layers, we believe the crystal settling mechanism of layer differentiation proposed by these workers was probably not important in the Bay of Islands complex. Goode³⁸ proposed an alternative mechanism involving differential crystal settling, not in conditions of continuous crystal nucleation, but in conditions of discontinuous nucleation. This model can, in theory, explain the existence of reversely stratified layers and can account for successively repeated uniform layers having a single cumulus (that is, primocryst) phase. Successively repeated uniform layers having more than one primocryst phase are, however, abundant in the transition zone and layered gabbroic units of the complex and they are often bounded by sharp form contacts²⁸ which involve no change in mineralogy, but simple changes in grain size, texture, or modal proportions. This type of layer sequence is not predicted or readily explained by this alternative model of layer development by differential crystal settling. We suggest that the sequences of layer types observed in the plutonic section of the Bay of Islands may be more appropriately interpreted in terms of in situ crystallization models rather than differential crystal settling models.

Comb layering^{34,39}, inch-scale layering⁴⁰ and intercumulus layering³⁸ are locally abundant in the plutonic section and constitute layer types which are interpreted to form by in situ crystallization processes^{28,29,36,38}. Colloform growth structures similar to those described within the marginal border group of the Skaergaard intrusion^{28,36} and layers exhibiting discontinuous protrusions which resemble reef-like growth structures and commonly contain elongate dendritic crystals oriented perpendicular to the regional strike of more normal layering are also commonly observed and can be interpreted in a similar fashion. Chromitites exhibiting chain textures occur in the ultramafic unit of the plutonic section and may imply in situ crystallization and/or heterogeneous nucleation²⁹. Oikocrystic textures characteristic of some wehrlitic and feldspathic dunites and some gabbroic rocks are difficult to interpret as the result of crystal settling and accumulation processes followed by in situ post-cumulus oikocrystic growth²⁵, rather, the lack of a selfsupporting crystal framework of supposed, smaller primocryst phases included within the larger, supposed post-cumulus oikocrysts may indicate a wholly in situ origin for these rocks. Considered with evidence on the discordancy of the fine-scale igneous layering, we interpret these data to indicate that the bulk of the plutonic section has formed as the result of nucleation and growth of crystals at the bounding surface of the magma chamber. Heterogeneous nucleation of crystals at the margins of the chamber may, in part, be the result of the very low degrees of super-cooling expected in the interiors of extremely large magma chambers at mid-ocean ridges.

Lateral continuity to thickness ratios of fine-scale layers are very small in comparison to most continental layered mafic intrusion^{28,40} and even the thickest layers can seldom be followed for more than 50 m along strike. While lithologically distinct megalens units within the plutonic sections can be followed for significant distances along strike (as much as 4 km), their constituent fine-scale layers are also lens-like pinching out in either direction along strike over as much as 50 m or as little as 1 m. If these layered plutonic rocks form due to in situ crystallization, the lack of lateral continuity must be interpreted as the result of fairly significant lateral changes in physico-chemical conditions on a scale approximated by the lateral continuity of the layering. This may indicate that the edges of the magma chamber were periodically or continuously characterized by a fairly stagnant boundary layer36 in which diffusion-controlled differentiation processes might be operative.

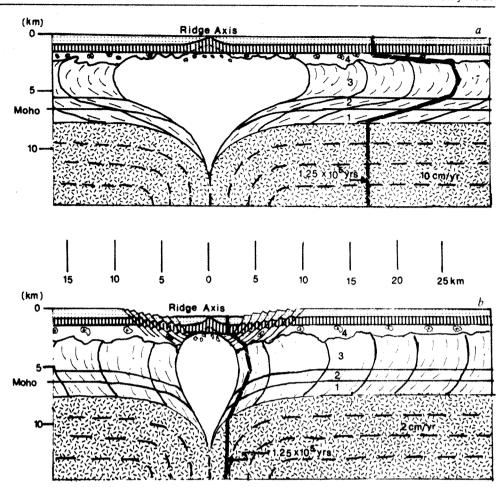

In the northern three massifs the arcuate shapes defined by cumulate layering are interpreted as profiles generated successively along one side of an elongate cylindrical magma chamber. We prefer to interpret this structure as the product of progressive growth of the plutonic assemblage as it rode first upwards and then laterally away from the spreading centre axis above a depleted-upper-mantle conveyor belt (Fig. 4). The suggested structure (Fig. 5) is very similar to a first approximation to the "infinite onion" model first proposed by Cann⁶. In fact, the details of the reconstructed profiles in the Bay of Islands complex are even more onion-like than those of Cann's theoretical model, however, the genetic distinctions made by Cann between cumulate, layered gabbro and isotropic, plated gabbro do not seem to apply here.

The magma chamber profiles and major lithologic units of the plutonic section observed in the Bay of Islands complex seem to be continuous and systematic and to lack large-scale truncations. This strongly suggests that a steady-state magma chamber was present. The longest axis of the chamber was parallel to the ridge axis; its ultimate length being limited by its truncation at fracture zone intersections. The minimum height of the magma chamber can be estimated from the thickness of the plutonic group to be ~6 km. While allowing for possible rotation of unit contacts in the structurally deepest regions due to the motion of the underlying residual upper mantle, reasonable estimates of maximum magma chamber height based on the North Arm Mountain structure would range from 6 to 8 km if measured at the precise ridge axis. Assuming bilateral symmetry, the width of the chamber could have been as much as 14-16 km based on the length of the clinopyroxenite megalens and the trajectory of fine-scale igneous layering in the overlying transition zone and gabbroic unit. Such a large magma chamber is not inconsistent with theoretical thermal calculations^{5,42} and seismic results^{2,3,14} for mid-ocean ridges with fast spreading

The magma chamber profiles described above appear to be quite variable as layering trends are often very irregular locally. Even in map areas adjacent to those described here similar large-scale arcuate structures are not well defined. These areas are characterized by highly variable discordant layer orientations and may reflect considerable unevenness in the morphology of the chamber walls in time and space. Some of these irregularities might evolve due to magma current erosion and/or the growth of reef-like protrusions formed by localized rapid growth at points along the walls²⁵. Localized fracturing and cooling of the crust by hydrothermal circulation might also cause cold spots along chamber walls where crystallization might occur at an accelerated pace.

In the Lewis Hills massif, an arcuate profile oriented approximately perpendicular to those in the northern massifs exists. This structure is interpreted as the result of vertical pinching-out

Fig. 5 Schematic models for the formation of oceanic lithosphere depicted by cross sections oriented perpendicular to a fast (10 cm yr half spreading rate) spreading centre (a) and a slow (2 cm yr spreading centre (b). Shading as in Fig. 2. a is based on the geology and approximate unit thick nesses observed for the North Arm Mountain section. intrusive/extrusive carapace of pillow lava, diabase and some underplated gabbro floating over magma chambers of different widths and different shapes are depicted. Chambers are situated over the diverging limbs of depleted upper mantle. Bold dashed lines indicate 1.25×10^5 yr isochrons. Bold solid lines depict the shapes of the steady-state magma chamber at various times in the past as determined from the arcuate patterns of fine-scale igneous layering (thin dashed lines). Note that the fine-scale igneous layering (or time lines) strike obliquely across the major lithologic subdivisions of the plutonic section reflecting chemical zontation of the magma chamber. Flow lines for the upper mantle and overlying crust are depicted by dashed lines in the residual mantle unit. Sea floor topography depends on the equilibrium size of the

magma chamber⁴⁵ which is ultimately determined by the spreading rate^{5,42}. The final fine-scale igneous layering geometry is determined by the size and shape of the former magma chamber.

of the magma chamber where it was truncated at a ridge-ridge transform fault. The structure seems to indicate that the lower surface of the magma chamber shallowed considerably at this intersection while the seafloor presumably deepened. Assuming no major change in the level of the top of the harzburgite unit, a relatively thin overlying gabbroic unit is inferred (Fig. 4b). Overall the structure suggests decreasing height of the magma chamber as the fracture zone intersection is approached. Lateral dimensional changes cannot be clearly resolved in the preserved layering geometry. Very irregular layering, abundant gabbro xenoliths, and periodotite plutons obscure the details of the layering in the central part of the Lewis Hills massif along the preserved magma chamber truncation. The increase in relative thickness of ultramafic cumulates in addition to the shallowing of the chamber floor could result in progressive shallowing of the Moho near fracture zones as documented by recent marine seismic refraction studies⁴³.

Model of plate accretion

A mid-ocean ridge environment represents a site of mantle upwelling as well as mantle divergence⁴⁴ in which the mantle flow direction makes a right angle turn from vertical beneath the ridge to horizontal on its flanks. In such a case the 'frozen in' mantle flow lines will be only moderately inclined to be horizontal on the ridge flanks. When viewed on a large scale this upwelling can be modelled in terms of divergent flow of a viscous fluid⁴⁵. As in any such viscous flow, the mantle flow rising and diverging beneath an oceanic ridge follows smooth curved paths. A sharp right angle turn of the flow lines is not possible because it would require infinite acceleration at the inflection point.

Nelson⁴⁵ has suggested that the surface of the upwelling mantle must, in effect, define an axial valley of some finite width and has modelled the variable topography along mid-ocean ridges in terms of mantle divergence and the equilibrium size of the sub-axial magma chamber.

The structural data from the tectonites of the upper harz-burgite section and the lowermost plutonic section of the Bay of Islands complex are consistent with the mantle upwelling model. The tectonite lineation direction, interpreted to lie close to the plastic flow direction, is subparallel to palaeohorizontal surfaces and subperpendicular to the mean dyke orientation. Both the foliation and lineation have been 'frozen' into a subhorizontal position which lies close to the predicted flow direction in the mantle ^{46–48}.

The contact between the rocks of the plutonic group and the residual harzburgite of the ophiolite which seems to be sub-horizontal represent an unconformity between rocks of magmatic origin and depleted upper mantle origin. The existence of this sharp contact requires the surface of residual mantle to intersect the base of the crustal level magma chamber at some time⁸. The most likely place for the creation of this contact is near the axis of divergence where the 'surface' of the upwelling residual mantle is, in essence, continually being created.

Because the lowermost plutonic section is affected by the same high temperature ductile deformation that affects the residual harzburgite, internal deformation must occur here while accretion of the plutonic section onto the surface of the upwelling mantle proceeds. The flow lines in the overlying plutonic rocks will grossly parallel the flow lines of the surface of the upwelling mantle as they are progressively accreted, while the carapace of the magma chamber which probably has a bulk

density equal to or less than the magma below²⁷ simply 'floats' on top of it. The carapace of the chamber, and therefore the sea floor, will not necessarily mirror the surface of the upwelling mantle until the entire thickness of the crust has solidified at the outermost extremity of the magma chamber. The equilibrium size of the magma chamber, largely dictated by spreading rate^{5,42}, will determine the ridge topography⁴⁵ (Fig. 5).

From the point of formation of the surface of the mantle (the axis of divergence) the plutonic section will gradually be accreted and thicken largely by heterogeneous nucleation and in situ crystallization at the bounding surface of the magma chamber, until at the outer margin of the steady state chamber the crust is completely solidified. The layer pattern preserved in plutonic section will outline the former surfaces of the chamber and therefore represent isochrons. Identification of a pattern will depend on regularity in the shape of the chamber, and if delineated, will conform to the size and shape of the magma chamber. The shape and size defined by the layering pattern is unlikely to be the same in every ophiolite and in the simplest case the equilibrium size of the chamber ultimately depends on spreading rate^{5,42}. Therefore, an estimate of relative spreading rate within ophilolites may be made using the chamber dimensions defined by these profiles. Where spreading rates are very slow or where non-steady-state episodic spreading occurs magma chambers may become so narrow that they periodically solidify completely. Large-scale truncations of the layered

structure and lithologic units would be expected to result in such cases. We see no such evidence at present in the Bay of Islands complex. Given this and the observed dimensions inferred from the layering profiles, a relatively fast spreading history is inferred. High temperature ductile deformation of the lower plutonic section in some cases may obscure the original angle of inter-

Regular well-preserved and ordered structures such as those described here may be rare in ophiolite complexes. However, identical patterns have been described for the Semail ophiolite49. On the other hand, if such relations have been overlooked or distorted by forcing all cumulate layering into a reconstructed subhorizontal orientation, as is commonly required, serious errors in layer thickness estimates could result. This might partially account for small apparent thicknesses of ophiolites relative to the seismic thickness of the oceanic crust12

Structure of the actin-myosin interface

Dominique Mornet, Raoul Bertrand, Pierre Pantel, Etienne Audemard & Ridha Kassah

Centre de Recherches de Biochimie Macromoleculaire du CNRS, Route de Mende (BP 5051), 34033 Montpellier Cédex, France

The topography of the rigor complex between F-actin and myosin heads (S1) has been investigated by carbodiimide zero-length cross-linking. The results demonstrate for the first time that the 95,000-molecular weight (95K) heavy chain of the myosin head enters into van der Waals contact with two neighbouring actin monomers; one is bound to the 50K domain and the other to the 20K domain of the myosin chain. The covalent F-actin-S1 complex can be isolated; it shows a vastly elevated Mg²⁺-ATPase. Each pair of actin subunits in the thin filament seems to act as a functional unit for specific binding of a myosin head and stimulation of its Mg²⁺-ATPase activity.

MUSCULAR contraction and cell motility are thought to operate by a cyclic displacement of myosin heads (S1 'crossbridges') along the actin filaments. The mechanical force is

generated at the myosin-actin interface and is coupled to Mg2+-ATP hydrolysis catalysed by the actin-myosin complex. The mechanism of the interaction is poorly understood.

The aims of the work reported here were to identify the participating elements and elucidate the main structural features

^{*} To whom correspondence should be addressed.

of the actin-myosin head interaction region and to establish the relationship of this van der Waals complex to actin activation of the myosin ATPase activity and cross-bridge function. Using a chemical cross-linking reaction as a molecular probe, we have investigated the mode of attachment of S1 heavy chain to F-actin in a variety of experimental conditions, and have identified the covalently associated actin-S1 entities formed. We have also determined the enzymatic properties of the myosin heads consequent on their irreversible attachment to F-actin in defined conditions.

Experimental strategy

Our experiments were based on three critical parameters. (1) Cross-linking reactions were performed on rigor complexes of F-actin using the following: native chymotryptic S1 (A1 + A2), S1 (A1), S1 (A2)1 and the three tryptically fragmented S1 derivatives²⁻⁴, the heavy chain of which is a complex of two or three fragments: (27K-50K-20K) (molecular weights 27,000-50,000-20,000)-S1, (27K-70K)-S1 and (75K-22K)-S1. These proteolytic S1 derivatives result from restricted tryptic hydrolysis of S1 in the absence and presence respectively of F-actin, which specifically modulates the breakdown of a 2K segment linking 50K and 20K fragments and confers protection against loss of actin-S1 Mg²⁺-ATPase³. All these derivatives interact reversibly with actin. The fragmented nature of their heavy chain allows direct identification of the parts of the chain which are engaged in cross-linking with actin. In preliminary experiments, cross-linking reactions were also carried out using heavy meromyosin (HMM)¹

(2) Before cross-linking, rigor actin-S1 complexes were prepared, in which either the actin or the S1 (or its derivatives) were labelled with the fluorescent dye N-(iodoacetyl)-N'-(1-sulpho-5-naphthyl)ethylenediamine (1,5-IAEDANS), the actin at cysteine 373 and the S1 at SH₁ thiol group³. This

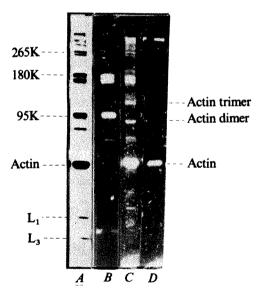

Fig. 1 SDS-gel electrophoretic analysis of actin-S1-containing crosslinked products. F-actin purified according to Spudich and Watt¹⁸ was weshed and equilibrated by sedimentation in 100 mM 2-N-morpholinoethanesulphonic acid (MES), pH 6.0, then immediately incubated (2.5 mg ml⁻¹) with 15 mM EDC (added as a solid) in the MES buffer for 2 min at 20 °C. A sample aliquot was mixed with 5-10 volumes of \$1 solution in the same buffer (final molar ratio of actin/S1 = 2). After 10 min at 20 °C, samples (=35 µg S1) were submitted to SDS-polyacrylamide slab gel electrophoresis (5-18% gradient acrylamide) using a 50 mM Tris/100 mM boric acid buffer system3. Gels were viewed using long-wave UV light and stained with Coomassie blue. Before use, F-actin or S1 was made fluorescent with 1,5-IAEDANS according to Takashi¹⁹ and Duke et al.²⁰, respectively. A, protein bands stained with Coomassie blue after reaction of S1 with EDCactivated actin; this pattern is unchanged when labelled S1 or labelled actin is used. B. fluorescent bands produced by reaction of IAEDANS-S1 with activated F-actin. C, fluorescent species produced by reaction of S1 with activated IAEDANS-actin. D, pattern of fluorescence in the EDC-activated IAEDANS-actin control. No change in S1 pattern was observed when the cross-linking reaction was processed in the absence of actin.

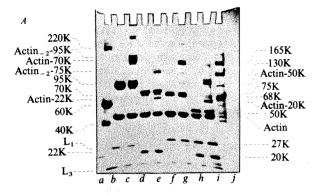

procedure allowed direct identification of actin and 20K peptide-containing material (SH₁ is located in the 20K unit⁵) in the observed cross-linked products. The molar ratios of actin/S1 present in cross-linked species were estimated quantitatively. This was done by measuring the ³H/¹⁴C ratio in the species resulting from cross-linking reactions performed on complexes of actin and S1, labelled at the sites mentioned above with ³H-iodoacetic acid and ¹⁴C-iodoacetamide, respectively.

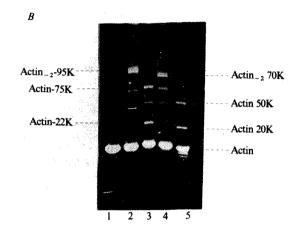

(3) Cross-linking reactions were catalysed with 1-ethyl-3 (3-dimethylaminopropyl)carbodiimide (EDC), a water-soluble carbodiimide that forms zero-length covalent bonds between amino and carboxyl groups in the contact area between two proteins. Most experiments were done using our highly versatile two-step procedure. First, actin was treated with EDC (activation phase), then an aliquot of the activated protein was mixed with a solution of S1, to give at least a fivefold dilution of the actin (condensation phase). This second step ensures a simultaneous quenching of the initial EDC reaction and covalent association of the two proteins. This procedure avoids most of the disadvantages of the usual one-step method; it suppresses intramolecular cross-linking when fragmented S1 or doubleheaded HMM are used, it allows the two phases of the reaction to be carried out separately in specific optimal conditions, and it also permits the controlled EDC-activation of either actin or S1 at will, and thus affords information on the compositions of both proteins at the interface.

Specific binding of 95K heavy chain to two vicinal actin subunits

Analysis of the products of reaction of EDC-activated actin with S1 (A1+A2) by gradient SDS-polyacrylamide slab gel electrophoresis gave the protein band pattern shown in Fig. 1A. It is characterized by the presence of two new components, both present as doublets. Estimations on calibrated 5-18% acrylamide gels indicated that the major species had Mrs of \sim 180,000 (185,000 and 175,000 for the components of the doublet), while that of the other, minor species was 265,000 (260,000 and 270,000). The distribution of the fluorescence in the protein bands formed from EDC-treated rigor complexes containing either fluorescent actin or fluorescent S1 demonstrated unequivocally that the two protein doublets were covalently cross-linked adducts of actin and S1, as label from either source was incorporated (Fig. 1B, C). They were sometimes accompanied by traces of two components which were fluorescent only when fluorescent actin was used and which were found in the EDC-actin control (Fig. 1D). Their electrophoretic mobility is consistent with their assignment as intramolecularly cross-linked actin dimers and trimers. The exact origin of the actin-S1 protein doublets is unknown but it does not arise from the heterogeneity associated with the presence of heads bearing different alkali light chains, as similar results were obtained with purified S1 (A1) and S1 (A2).

While the minor 265K product is sometimes absent, the major 180K derivative is always abundant in a wide range of experimental conditions (pH 6-7.5 at 0-20 °C and ionic strength 0.01-0.1 M in non-nucleophilic buffer). In optimal conditions ~30% of S1 becomes covalently bound to F-actin as determined by sedimentation (see below). However, no cross-linking occurs when activated actin is reacted with S1 in the presence of -pyrophosphate or Mg²⁺-ATP (5 mM), which are known to dissociate the actin-myosin complex, and more importantly, no covalent association can be obtained between native actin and EDC-activated S1 (although the reagent does react appreciably with \$1 carboxyl groups in the standard conditions of the activation reaction). The absence of covalent links between activated S1 and actin is not due to any effect of EDC on the reversible association between S1 and actin, as the 180K product is readily formed when the cross-linking reaction is done using the conventional one-step procedure. Therefore the 180K complex seems to be the result of a very specific crosslinking process which requires the formation of a bimolecular

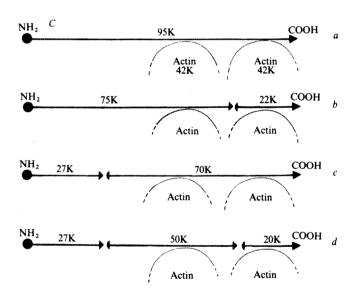

Fig. 2 Mapping of the heavy chain segments bound to the actin subunits by cross-linking the trypsin-modified S1 derivatives to fluorescent F-actin. The tryptically fragmented S1 species were prepared as described elsewhere and condensed to EDC-activated IAEDANS-actin as described in Fig. 1 legend; the same procedure was followed for native S1. Samples were analysed by electrophoresis on 5-18% acrylamide slab gels. A, protein banding pattern after staining with Coomassie blue. Lanes a and j, protein markers: ferritine (M, 220,000), y subunit of Escherichia coli RNA polymerase (165,000), β -galactosidase (130,000), bovine serum albumin (68,000), catalase (60,000), aldolase (40,000). Lanes b and c, native S1+ labelled actin before and after cross-linking. Lanes d and e, labelled actin + (75K-22K)-S1 before and after cross-linking. Lanes f and g, labelled actin+(27K-70K)-S1 before and after cross-linking; h and i, labelled actin + (27K-50K-20K)-S1 before and after cross-linking. B, location on gel of fluorescent actin-containing cross-linked products. Lane 1, fluorescent actin control; 2, fluorescent actin cross-linked to native S1; 3, fluorescent actin cross-linked to (75K-22K)-S1; 4, fluorescent actin cross-linked to (27K-70K)-S1; 5, fluorescent actin cross-linked to (27K-50K-20K)-S1. C, schematic diagram illustrating the relationship of the two actin subunits to the segments of myosin head heavy chain. a, Native S1; b-d, typically fragmented S1 derivatives.

 3 H-carboxymethyl actin (prepared according to Takashi et al. 23) (~ 2.0 3 H per mol protein, 18 mCi mmol $^{-1}$) was activated with EDC and reacted with 14 C-carboxyamidomethyl S1 (obtained by the same precedure: ~ 1.5 14 C per mol protein, 45 mCi mmol $^{-1}$) as described in Fig. 1 legend. Samples ($\sim 100~\mu g$ S1) were subjected to SDS-polyacrylamide gel electrophoresis (4-18% acrylamide gradient). After staining with Coomassie blue, the 180K protein doublet was isolated as a gel slice; two slices were combined and treated with 1 ml of Soluene 100 at 40 $^{\circ}$ C for 4 h. Radioactivity was measured in 10 ml of scintillator using a Packard 3003 counter. Contribution of 3 H to 14 C counts was subtracted using 3 H $^{-14}$ C calibration mixtures. The data shown are from different cross-linking experiments.

complex in which EDC-activable carboxyl groups on the actin are in contact with nucleophilic, probably amino groups on the myosin heads. This conclusion agrees with the suggestion made by Bárány and Bárány⁶ that the actin-myosin complex is a polyelectrolytic system in which the actin behaves as a polyanion and the myosin as a polycation. In addition, the ionic strength dependence of the rate constant of association of actin with S1 (ref. 7) indicates an ion-paired charge interaction at the recognition site.

The apparent mass of the 180K species containing both S1 and actin suggested that it must be generated by the association of two actin monomers with a single 95K heavy chain. The first direct evidence for this composition was obtained by determining the ³H/¹⁴C ratios of the 180K protein doublet formed by cross-linking ³H-actin to ¹⁴C-S1. The results showed an average ratio of ~2 which indicates a stoichiometry of two actin subunits per head (Table 1). Peptide mapping of the cross-linked species formed by complexes of fluorescent actin with the three tryptically fragmented S1 derivatives (Fig. 2A, B) not only confirmed this result but also led to the important conclusion that the two actin subunits are not associated by intermolecular EDCinduced cross-links but rather are separately and specifically bound to two different segments of the 95K heavy chain, that is, 50K and 20K fragments. Thus (75K-22K)-S1 gives rise to two new fluorescent cross-linked products, actin-75K peptide (M_r = 120,000; 120K) and actin-22K peptide ($M_r = 64,000$) (Fig. 2A, lanes d and e; B, lane 3). When (27K-70K)-S1 is used, the two actin subunits are both bound to the intact 70K segment to form the new cross-linked species (actin₂-70K peptide ($M_r = 155$ -160,000), Fig. 2A, lanes f and g; B, lane 4). The two actinbinding domains present in (27K-50K-20K)-S1 can be characterized by their ability to cross-link to the pair of actin monomers, yielding actin-50K peptide ($M_r = 94,000$) and actin-20K peptide ($M_r = 62,000$) (Fig. 2A, lanes h and i; B, lane 5). Interestingly, only the actin₂-70K peptide complex, containing two actin monomers, yields a doublet on the gel; all the other species, including actin-75K peptide, contain a single actin subunit and migrate as single bands. This suggests that the observed electrophoretic heterogeneity may be due to the presence of the pair of actin molecules. We have confirmed the distribution of the actin pair between the various heavy chain segments (see Fig. 2C) by repeating the above observations with fluorescent fragmented S1. Moreover, when the reaction mixture of EDC-activated fluorescent actin-S1 was treated with trypsin², a large amount of actin₂-70K fragment was liberated, together with smaller proportions of actin-20K peptide and actin-50K peptide, which indicates that the actin subunits are dispersed in a similar manner on intact S1 and its fragments. We have failed to observe a cross-linked species corresponding to

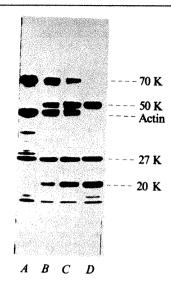

Fig. 3 Relationship between S1 binding to actin and the tryptic sensitivity of the 95K heavy chain (at low ionic strength, excluding any effect of salt on the S1-actin binding affinity). Tryptic conversion of actin-bound S1 into actin-activable (27K-70K)-S1 and actin-nonactivable (27K-50K-20K)-S1 derivatives. Samples A, B and C were analysed by electrophoresis as described in Fig. 1 legend; S1 fragmented in the absence of actin was used as control (lane D). Molar ratios of actin/S1 present in the digestion mixture were A = 2, B = 1 and C = 0.5.

the direct association between a single actin monomer and the intact or fragmented 95K heavy chain.

A cross-linking study was carried out at different actin/S1 molar ratios (0.5-10) to investigate conditions which favour the formation of the 265K derivative; this showed that the amount of the 180K component alone increases with increasing concentration of actin, reaching a maximal value at an actin/S1 molar ratio near 2. In contrast, yield of the cross-linked 265K component remains rather low even at an actin/S1 ratio of 1, although further studies (see below) showed that all S1 molecules are bound to actin at this ratio. Thus we assume that rigor attachment of an actin pair to the first S1 molecule imposes a different geometry on the binding of the second S1 molecule. This difference emerges from the capacity of the activated actin carboxylates to cross-link the first S1 compared with the much less efficient attachment of the second S1 at the topologically equivalent second site. This is indicative of the steric nonequivalence of the two heads in the complex.

Strong support for this scheme comes from a parallel study undertaken to define the relationship between the tryptic sensitivity of the 50K-20K junction of S1 heavy chain and the relative amount of actin needed to protect it. The actin-S1 ATPase activity, which depends on the structural integrity of the 50K-20K join³, is insensitive to trypsin at actin/S1 molar ratios ≥2. Below a ratio of 2 it decreases, and at a ratio of 1, when all S1 molecules are bound to actin as assessed by turbidimetry and sedimentation⁸, ~50% of this enzymatic activity is lost. The gel electrophoretic pattern of the tryptic digest of an equimolar mixture of actin and S1 (Fig. 3) clearly indicates the formation of two types of S1 derivative in equimolar amounts: (27K-70K)-S1 (ATPase activity activable by actin) and (27K-50K-20K)-S1 (ATPase activity not actin activable). At the critical molar ratio of actin/S1 = 2, only the former active derivative is present. Thus trypsin is able to discriminate between the two kinds of S1 bound to the same actin dimer unit, these being the 'trypsinsensitive' and 'trypsin-insensitive' species (Fig. 5). We obtained similar results with both S1 and myosin in other ionic conditions³. In this regard, the tryptic susceptibility of the 50K-20K junction of S1 heavy chain seems to be an excellent probe of the mode of attachment of the head to actin. It indicates also that the

protective action of F-actin towards the 50K-20K join^{2,3} is not due to the simple binding of S1 to actin but rather requires a specific actin-head recognition interface generated by the association of an actin dimer with a single S1 molecule in the absence of nucleotide. This mode of actin-head rigor interaction probably also occurs in vivo, as suggested by the findings of Lovell and Harrington⁹ on the tryptic susceptibility of rabbit skeletal myofibrils in physiological rigor conditions.

Covalent F-actin-S1 complex

Because the actin- and nucleotide-binding sites in myosin are coupled10, we have examined the effect of covalent association of S1 with actin on its Mg2+-ATPase activity. We found that the Mg²⁺-ATPase activity was greatly increased, and Fig. 4A, B shows that the extent of the enhancement depends on the time courses of the activation of the actin by EDC and of the attachment of S1 to the activated actin. The extent of Mg2 ATPase activation is apparently related to the amount of 180K product formed; it increases with increasing actin concentration and reaches a plateau at an actin/S1 molar ratio near 2. Conditions (see above) which suppress the 180K species also eliminate the ATPase activation. Control experiments have shown that P. liberation is not induced by the small amount of free actin accompanying S1 in the ATPase assay; in addition, this ATPase, in contrast to that of the reversible actin-S1 complex, is not affected by increased ionic strength. Finally, a parallel decrease in K⁺-ATPase of the EDC-activated actin-S1 mixture accompanies Mg²⁺-ATPase stimulation (Fig. 4B). We conclude that only the fraction of S1 that is covalently bound to actin is responsible for this new enzymatic behaviour and is able to catalyse massive hydrolysis of Mg²⁺-ATP. This is demonstrated by ultracentrifugal fractionation of the EDC reaction mixture in the presence of Mg²⁺-pyrophosphate into soluble and insoluble S1-containing fractions. The supernatant contains only residual S1 (Fig. 4C, lane 2) with unmodified enzymatic activity, but the pellet consists of irreversibly actin-bound S1 (Fig. 4C, lane 3) and shows elevated Mg2+-ATPase, the K+-ATPase being close to zero. The former activity remains unchanged when assayed in the presence of an added excess of free actin.

On the basis of the amount of S1 covalently linked to actin, estimated spectrophotometrically from the concentration of the enzyme in the supernatant⁸, we have calculated the specific Mg^{2^+} -ATPase activity to be $22\pm2~\mu\mathrm{mol}~\mathrm{P_i}$ per min per mg actin-bound S1, which corresponds to a turnover rate of $40~\mathrm{s}^{-1}$. When compared with the initial value of $0.02~\mu\mathrm{mol}~\mathrm{P_i}$ per min per mg actin-bound S1 (turnover rate = $0.036~\mathrm{s}^{-1}$ in agreement with reported values¹), this represents at least a 1,000-fold increase in the ATPase; the turnover rate of the covalent actin-S1 complex is strikingly similar to the V_{max} of the usual actin-activated ATPase of S1 (A1 + A2) extrapolated to infinite actin concentration¹. We refer to this unprecedented acceleration of Mg^{2^+} -ATP hydrolysis catalysed directly in vitro by actin-bound S1 as 'superactivation', to differentiate it from any other activation process observed for this myosin activity in vitro

Conclusions and implications

On the basis of these results we conclude that each actin monomer has two heavy chain-binding regions, specific for the 50K and 20K elements, respectively. The myosin head-binding unit of the thin filament in rigor conditions would thus be a contiguous actin pair. Consequently each functional pair of neighbouring actin monomers must have two pairs of head sites allowing the stoichiometric binding of a pair of heads (Fig. 5). This is supported by the occurrence of the 265K species which comprises actin and S1 and whose apparent mass agrees with its identity as the product of a pair of 95K heavy chains cross-linked with a pair of actin molecules.

Our results agree with the model recently proposed by Namba et al. 11 for the thin filament structure of crab striated muscle

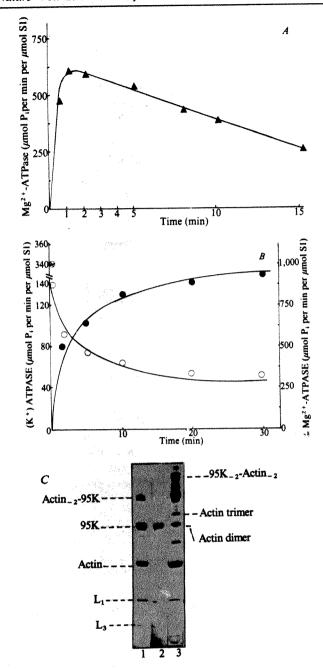

Fig. 4 Superactivation of the $\mathrm{Mg^{2^+}}$ -ATPase of S1 covalently bound to EDC-activated F-actin. A, dependence of the $\mathrm{Mg^{2^+}}$ -ATPase stimulation on the time course of actin activation by EDC. F-actin (2.5 mg ml⁻¹) in 100 mM MES buffer, pH 6.0, was reacted at 20 °C with 15 mM EDC (added as a solid). At the times indicated, a protein aliquot was withdrawn and mixed with 10 volumes of \$1 solution in the same buffer (final molar ratio of actin to S1 = 2); after 10 min of condensation reaction at 20 °C, samples (20 μg S1) were assayed for Mg²⁺-ATPase²¹. B, dependence of the Mg²⁺-ATPase stimulation and K+-ATPase inhibition on the time course of S1 condensation to EDC-activated actin. F-actin was first activated with EDC for 2 min, then mixed with S1 in conditions described above for A. At different times in the condensation reaction, S1 samples, 20 µg and 25 µg, were taken in parallel and assayed for ${\rm Mg}^{2+}$ -ATPase and ${\rm K}^+$ -ATPase, respectively 21 . \blacksquare , Acceleration of ${\rm Mg}^{2+}$ -ATPase activity, and \bigcirc , loss of ${\rm K}^+$ -ATPase activity of S1 covalently bound to actin. As reversible binding of S1 to actin inhibits the K^+ -ATPase at zero time of the cross-linking reaction²², the K^+ -ATPase was assayed in the presence of actin (actin/S1 ratio = 2); the value found was 60% lower than that given by free S1 (⊗). C, selective separation of the covalent actin-\$1 complex. After a 10-min period of condensation between activated actin and S1, the reaction medium was adjusted to 10 mM sodium pyrophosphate, 100 mM KCl, 5 mM MgCl₂ and 50 mM HEPES pH 7.5; after centrifugation at 140,000g for 45 min at 4 °C, the pellet was gently resuspended in the initial volume of a solution containing 10 mM KC 1.5 mM MgCl₂ and 50 mM Tris-HCl pH 8.0. It was subjected, together with the supernatant, to electrophoresis on gradient acrylamide gel as described in Fig. 1 legend. Lane 1, total reaction medium; lane 2, supernatant containing unreacted dissociable S1; lane 3, pellet containing nondissociable S1, covalently bound to the actin filament as major actin 2-S1, and minor actin 2-S12 species.

analysed by X-ray diffraction, which showed myosin heads attached to pairs of adjacent actin monomers. Actin-20K peptide and actin-50K peptide are now being isolated for elucidation of the points of contact between actin and the two heavy chain segments. Experiments in progress have also indicated EDC-induced cross-linking of actin dimers to the heavy chains of HMM, with concomitant superactivation of the Mg²⁺-ATPase. These data, together with those for the parent myosin, will be reported in detail elsewhere; the use of myosin is of particular interest because it contains molar amounts of LC2 light chain, the presence of which is reported to change the shape of the attached heads¹².

The covalent actin-S1 complex hydrolyses Mg²⁺-ATP at a very high rate because of the irreversible occupation of the actin site on S1. This provides the first direct experimental evidence for the possible non-dissociating pathway of ATP hydrolysis by actin-S1^{13,14}. Cross-linking of actin to S1 does not impair the catalytic properties of the enzyme but, on the contrary, preserves the active conformation of the ATPase site resulting from the interaction of actin with S1. The covalent actin-S1 material offers a valuable tool for investigating the kinetic parameters of ATP hydrolysis by actin-bound S1 and for determining the nature of the conformational changes transmitted to the ATPase site when the actin site is bound.

The ability of S1 covalently complexed to actin to hydrolyse ATP at an effective rate as high as that which normally occurs in the presence of infinite actin concentration should be considered in relation with the report of Bárány and Burt¹⁵ which indicates that in vivo contraction is associated with 1,500 -5,000-fold activation of myosin ATPase, which has never been seen in any in vitro system. Our covalent actin-S1 derivative may represent the first assembly in vitro of interacting actin-head complex resembling that found in the native cell.

The rigor association of S1 heavy chain with an actin dimer seems to be closely related to the molecular mechanism of stimulation of myosin Mg²⁺-ATPase by F-actin. Estes and Gershman¹⁶ have shown that neither G-actin nor F-actin monomers can activate the ATPase; they have concluded that the specific activating ability of F-actin is possibly formed or is stabilized by the association of two adjacent subunits. In addition, Fasold *et al.*¹⁷ have reported that isolated, non-polymerizable actin dimers generated by chemical cross-linking of F-actin bind stoichiometrically to S1 and activate the ATPase

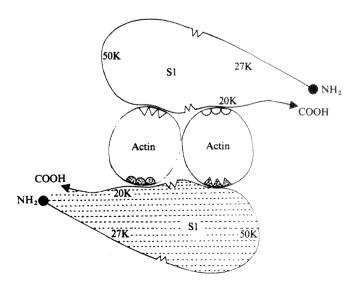

Fig. 5 Schematic diagram for stoichiometric binding of S1 to two actin monomers which are on two strands of the actin helix: hatched S1 is only poorly cross-linked, trypsin-sensitive S1; open S1 is strongly cross-linkable, trypsin-insensitive S1 (tryptic sensitivity is implicitly related to the splitting of the 50K-20K join).

25% relative to F-actin. Our results strongly support all these observations and further suggest that the proper positioning of the actin pair on the 50K and 20K segments of the heavy chain is a prerequisite for, at least, the initiation of the ATPase activa-

Gene conversion between duplicated genetic elements in yeast

Jennifer A. Jackson & Gerald R. Fink

Section of Biochemistry, Molecular and Cell Biology, Wing Hall, Cornell University, Ithaca, New York 14853, USA

The mitotic recombination behaviour of a duplication of the his4 region on chromosome III in the yeast Saccharomyces cerevisiae was studied. The major recombination event between the duplicated segments is gene conversion unassociated with reciprocal recombination. The rad52-1 mutation preferentially decreases mitotic gene conversion. These results suggest that mitotic gene conversion may occur by a different pathway from that occurring in meiosis. This mitotic gene conversion may be important in yeast mating type interconversion and the maintenance of sequence homogeneity in families of repeated eukaryotic genes.

GENETIC recombination is the result of an exchange between homologous regions of DNA and can occur between two segments located on homologous chromosomes, or between repeated segments of DNA on the same chromosome. Two types of homologous recombination have been observed in yeast and other organisms; reciprocal and non-reciprocal exchange, or gene conversion (reviewed in refs 1-3). In yeast, meiotic gene conversion is associated with reciprocal recombination4; as many as half the conversion events are accompanied by reciprocal recombination of flanking markers, and this conversion-associated recombination is frequent enough to account for all the genetic exchange observed in yeast meiosis. Current models for meiotic recombination postulate an exchange of DNA strands between homologous DNA duplexes^{1-3,5,6}. If there are base sequence differences between the two duplexes, the resulting structure contains a local region of heteroduplex. Gene conversion is believed to be due to the correction of the heteroduplex region. These models postulate that resolution of the heteroduplex results in recombination of flanking markers in

Increasing evidence suggests that mitotic recombination may occur by different pathways from those of meiotic recombination. In mitosis, gene conversion is not as closely associated with reciprocal exchange^{7,8}. Roman⁷ found that UV-light irradiation enhanced mitotic reciprocal recombination more than gene conversion, and that nitrosoguanidine enhanced gene conversion preferentially. In addition, Boram and Roman have isolated an allele of rad18 that enhances spontaneous mitotic gene conversion, but not reciprocal recombination. A further difference between mitotic and meiotic recombination in yeast is seen in the effects of other mutations. The reml-1 mutation enhances both types of exchange in mitosis, but has no effect on meiotic recombination 10,11. In contrast, the rad52-1 mutation abolishes meiotic recombination, but only decreases mitotic exchange 12-14. Thus, in mitosis, gene conversion and reciprocal recombination can be separated from each other. These considerations suggest that there may be mechanistic differences between meiotic and mitotic recombination.

We have used hybrid plasmids containing yeast DNA linked to an Escherichia coli plasmid to study mitotic recombination. During transformation these hybrid plasmids integrate by a homologous recombination event and create a direct duplication of the yeast DNA separated by plasmid sequences¹⁵. We have constructed a direct duplication of a 24-kilobase (kb) BamHI fragment on chromosome III which contains the his4 gene. By genetic techniques, different mutations were introduced into each of the two copies of the his4 gene, creating a duplication with the structure his4A pBR313 his4C. Mitotic recombination between the two his4 mutant genes can yield a HIS4+ recombinant. Whether the event which generated the recombinant was gene conversion or reciprocal recombination can be determined by analysis of the recombinants. A reciprocal

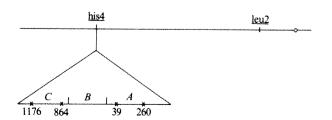

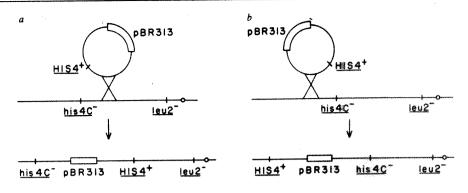

Fig. 1 Map of chromosome III. The his4 region is shown subdivided into A, B and C. The relevant his4A and his4C mutations are shown.

Fig. 2 Formation of duplication strains by transformation. The plasmid YIP300, which consists of a BamHI fragment carrying the HIS4⁺ gene inserted into pBR313, is shown to integrate into the yeast chromosome III by a homologous recombination event. The recombination event can occur centromereproximal or centromere-distal with respect to the his4C mutation on chromosome III. a, Orientation of the two his4 genes if the exchange event occurs proximal to the centromere; b, orientation of the two his4 genes if the exchange event occurs distal to the centromere. The line represents yeast DNA and the box represents pBR313 sequences.

recombination event gives rise to a HIS4⁺ segregant which has lost the duplication and the intervening plasmid sequences (see Fig. 4). A gene conversion event between the two elements of the duplication yields a HIS4⁺ segregant which has retained the duplication and the intervening plasmid sequences. Thus, a large number of mitotic recombinants can be scored as gene convertants or reciprocal recombinants by colony hybridization using plasmid DNA as a probe¹⁶. Using strains carrying duplications of the his4 region, we have shown that gene conversion, not associated with reciprocal recombination, is the major event giving rise to HIS4⁺ segregants in mitosis. Our studies of these strains also show that the rad52-1 mutation preferentially decreases mitotic gene conversion.

Construction of the duplication strains

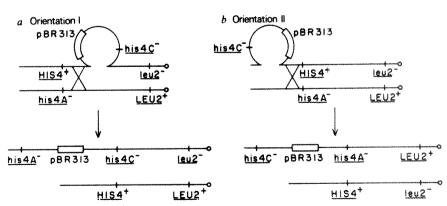

Yeast strains duplicated for the his4 gene were constructed by transformation¹⁵. The donor DNA was plasmid YIP300 which contains ~24-kb BamHI fragment of yeast DNA inserted into the BamHI site of the vector pBR313¹⁷. The HIS4⁺ gene is located near the middle of this BamHI fragment. The recipient was a haploid yeast strain containing two his4C mutations (his4-864 and his4-1176) and the leu2-3 mutation on chromosome III (Fig. 1). Transformation of this stable Hisstrain to HIS4⁺ occurs by the integration of the YIP300 plasmid by homologous recombination. Integration of this plasmid creates a duplication of the his4 region in one of two possible orientations. The orientation of the HIS4⁺, pBR313 and his4⁻ sequences with respect to leu2 depends on the site of integration

relative to the his4C mutations (Fig. 2). The HIS4⁺ transformants in either orientation are unstable—this instability results from mitotic recombination between elements of the duplication that give rise to his4⁻ segregants, and was also observed in yeast strains carrying a duplication of the leu2 region created by transformation¹⁵.

We devised a positive selection for recombination events in the duplicated region using strains in which each of the two copies of the his4 gene carry different mutations that can recombine to yield a HIS4⁺ segregant. These strains were constructed by crossing individual HIS4⁺ leu2⁻ transformants with a LEU2⁺ strain carrying two mutations in the his4A region: his4-260 and his4-39. A His duplication strain with the structure his4A⁻ pBR313 his4C⁻ (his4-260, his4-39, pBR313, his4-1176, his4-864) can arise from this cross by meiotic recombination event (Fig. 3). Crosses of individual transformants with a his4A⁻ LEU2⁺ strain give rise to recombinant His duplication strains of two orientations (Fig. 3). Both orientation I (his4A⁻ pBR313 his4A⁻ LEU2⁺) frequently give rise to HIS4⁺ segregants by mitotic recombination events.

When the HIS4⁺ transformants are crossed by the his4A⁻ strain, one parent has the standard arrangement on chromosome III and the other has an insertion of pBR313 flanked by a direct duplication of his4. Tetrad analysis of these crosses indicates that neither the duplication nor the pBR313 sequences affect meiotic recombination in the his4-leu2 interval. Analysis of 101 tetrads yielded a map distance between his4 and leu2 of 16.8 centimorgans, which is similar to the his4-leu2

Fig. 3 Formation of his4 duplication strains of orientations I and II. Transformation with YIP300 yielded duplications of the his4 alleles in two orientations (Fig. 2). Individual His transformants of both orientations were crossed by a LEU2 strain carrying two mutations in the his4A region (his4-260 and his4-39). Four types of His progeny resulted from this cross; three of these are completely stable and carry a single his4 region. Colony hybridization using plasmid DNA as the probe shows that they have no plasmid sequences. Stable His progeny are: (1) a non-recombinant which contains the two his4A mutations (his4-260 and his4-39); (2) a recombinant which contains the two his4C mutations (his4-1176 and his4-864);

and (3) a recombinant carrying all four mutations (his4-260, his4-39, his4-1176 and his4-864). The fourth type is a recombinant which contains a duplication of the BamHI fragment. The formation of this recombinant is shown. One element of the duplication contains the his4A mutations and the other contains the his4C mutations. The orientation of these mutations in the duplication depends on the site of integration of the YIP300 plasmid into the chromosome (see Fig. 2). The Leu phenotype of these recombinants is indicative of the orientation of the alleles in the duplication. The His recombinants carrying a duplication can be easily detected because they frequently give rise to His segregants by mitotic recombination events occurring between the two his4 regions, whereas the other His progeny are completely stable. Colony hybridization using plasmid DNA as a probe shows that the unstable His progeny retain the pBR313 sequences. Crosses of these strains with wild type (HIS4+) give rise to recombinant His progeny containing one or the other component of the duplication. The segregation of each of the components of the duplication in these crosses confirmed the structure in the duplications. a, The recombination event giving rise to a his4 duplication strain of orientation II. The thin line represents yeast DNA and the box represents pBR313 sequences.

Table 1 Frequency of HIS4+ formation in duplication strains

	3	1.0	2.2 ± 1.1		2	2.4	2.5 ± 0.6

A single colony of the strain to be tested was inoculated into 5 ml of liquid YEPD medium⁵¹ and grown to a concentration of $\sim 10^7$ cells per ml. Cultures were washed, diluted and plated on to five YEPD agar plates for a total cell count and on to five minimal agar plates to estimate the frequency of His⁺ colonies. The plates were incubated at 30 °C for 3 days before counting. The frequency of His⁺ cells was determined by dividing the number of His⁺ cells per ml by the total number of cells per ml.

distance (17.4 centimorgans¹⁸) found in crosses where both parents had the standard arrangement.

Mitotic recombination in haploids and diploids

Mitotic recombination occurs more frequently between two his4 genes located on a single chromosome III in a haploid than does recombination between his4 genes located on different chromosome IIIs in a diploid. The spontaneous mitotic recombination behaviour of duplications was studied using haploid strains in which one element of the duplication contained the his4A mutations and the other contained the his4C mutations. The frequency of HIS4+ formation was measured in these his4 duplications when the alleles were in both orientation I and orientation II. HIS4+ formation was also measured in heteroallelic diploids (his4A-/his4C-) of normal chromosome structure. Heteroallelic diploids of mating type a/a and α/α were studied in addition to an a/α diploid. Formation of HIS4 recombinants occurred with a frequency of 0.6×10^{-5} in a/α diploids, 0.1×10^{-5} in a/a diploids and 0.2×10^{-5} in α/α diploids. The haploid his4 duplication strain of orientation I gave rise to prototrophs at a frequency of 21.7×10^{-5} . Orientation II duplications gave rise to prototrophs at a frequency of 8.1×10^{-5} (Table 1). (The difference in frequency between orientations I and II is not statistically significant (P > 0.90). Thus, duplications recombine at a frequency which is at least an order of magnitude greater than that measured in diploids.

In meiosis, a diploid containing a duplication on each

homologue (his4C⁻ pBR313 his4C⁻/his4A⁻ pBR313 his4C⁻) yields His⁺ recombinants in 1.6% of the tetrads (2/123). Our finding that the frequency of recombination in mitosis is rare compared with that in meiosis agrees with all previous studies on recombination in yeast^{4,7-11}.

Gene conversion is the major recombination event

To study the mitotic recombination events which occur between elements of a duplication, the HIS4+ recombinants arising from haploid duplication strains were analysed by colony hybridization using pBR313 DNA as the probe. The presence or absence of pBR313 is indicative of the event which gave rise to the HIS4+ recombinant. Gene conversion unassociated with reciprocal recombination will give a HIS4+ recombinant which retains the two copies of the his4 region and the pBR313 sequences (pBR313⁺). A HIS4⁺ recombinant with a single copy of the his4 region and no pBR313 sequences (pBR313-) can be generated by two types of event. The first is a simple reciprocal recombination event between the mutant alleles (see Fig. 4). Alternatively, gene conversion of one of the His alleles to His. followed by reciprocal recombination will give rise to a Hist pBR313 recombinant. These two events cannot be distinguished from each other, but as both involve reciprocal exchange they will be classified together as reciprocal recombination

Analysis of HIS4⁺ recombinants arising from duplications in orientation I showed that 15 (12%) had lost the pBR313

Table 2 Frequency of gene conversion and reciprocal recombination among HIS4⁺ recombinants

		Colony	hybridization

96-40B	rad52-1	2.6	146	59†	41	0.18	2.4

Frequency of recombination was determined by dividing the number of prototrophs per ml by number of cells per ml. Mean frequency of recombination is the arithmetic average of frequencies shown in Table 1. Mean frequency of gene conversion was calculated by multiplying % gene conversion, as determined by colony hybridization and Southern analysis, by mean frequency recombination. Mean frequency of reciprocal recombination was calculated by multiplying % reciprocal recombination, as determined by colony hybridization and Southern analysis, by mean frequency recombination.

^{*} Southern hybridization analysis of eight independent His⁺ recombinants showed that 1/4 were triplications and 3/4 were duplications of the his4 region (see Fig. 5).

[†] Southern hybridization analysis of eight independent His⁺ recombinants showed that 7/8 were triplications and 1/8 were duplications of the his4 region (see Fig. 5).

Fig. 4 Formation of HIS4⁺ prototrophs by reciprocal recombination. a, Reciprocal recombination in orientation I. In G1, before DNA replication, an intra-strand event will yield a HIS4+ recombinant with a single copy of the his4 region, and a circular molecule carrying both his4 mutations and pBR313. In G2, after DNA replication, an inter-strand event will yield a HIS4* recombinant with a single copy of the his4 region, and a his4 recombinant with three copies of the his4 region and two of pBR313. b, Reciprocal recombination in orientation II. In G2, an inter-strand event will yield a HIS4+ recombinant with three copies of the his4 region and two copies of pBR313. The his4 recombinant has a single copy of the his4 region. In G1, a simple reciprocal recombination event cannot yield a HIS4+ recombinant. The thin line represents yeast DNA and a box represents pBR313 sequences.

sequences and 112 (88%) had retained them (Table 2). Southern analysis of total yeast DNA using the BamHI fragment of his4 DNA as a probe showed that the His⁺ pBR313⁻ recombinants have a single copy of the his4 region. This analysis indicates that the recombinants which lose the pBR313 sequences are the result of reciprocal recombination. Confirmation that the major class of recombinants, His⁺ pBR313⁺, arose by gene conversion comes from two lines of evidence. First, Southern analysis using the BamHI fragment of his4 DNA as a probe showed that these recombinants retain two copies of the his4 region. Second, when any individual His⁺ pBR313⁺ recombinant was crossed by an untransformed HIS4⁺ strain, either his4A⁻ or his4C⁻ progeny were recovered. This result indicates that in orientation I most recombinants result from gene conversion.

Most HIS4⁺ recombinants which were produced by his4⁻ duplications in orientation II were also due to gene conversion. There are three types of HIS4+ recombinants which result from this orientation. The first type is one which retains the two copies of the his4 region and one copy of the pBR313 sequences—this type of HIS4⁺ recombinant results from a gene conversion event unassociated with reciprocal exchange. The second type is a HIS4+ recombinant which carries a triplication of the his4 region and two copies of the pBR313 sequences. This type can be generated by an uneven reciprocal recombination event between sister chromatids (Fig. 4). The third type has a single copy of the his4 region and no plasmid sequences. This type could result from the conversion of one of the mutant alleles to His*, followed by a reciprocal recombination event, or alternatively from triple crossovers. Both types 2 and 3 are classified as reciprocal recombinants because their formation involved a reciprocal exchange.

Analysis of 199 $HIS4^+$ recombinants arising from a strain carrying the duplication in orientation II showed that 193 (97%) had retained pBR313 and 6 (3%) had lost pBR313 (Table 2). To determine which fraction of the His⁺ pBR313⁺ recombinants is due to gene conversion, Southern analysis using plasmid DNA as a probe (Fig. 5) was performed on eight independent His⁺ pBR313⁺ recombinants. This experiment showed that six of the eight recombinants had two copies of the his4 region and two had three copies. Assuming that these independent isolates are representative of the whole population, we conclude that ~25% of the $HIS4^+$ recombinants from orientation II strains are due to reciprocal recombination and 75% are due to gene conversion.

Our finding that most of the HIS4⁺ recombinants from the

duplication strains are gene convertants agrees with previous studies on recombination in yeast. Intragenic recombination both in mitosis and meiosis is usually a result of gene conversion rather than reciprocal recombination ^{19,20}. It has been shown that up to half of the meiotic conversion events are associated with reciprocal recombination⁴. In contrast, the major mitotic recombination event observed in duplications is gene conversion, unassociated with reciprocal exchange. Our evidence for this conclusion is based on the retention of the duplication and plasmid sequences in most HIS4⁺ recombinants. This result agrees with studies of mitotic recombination in diploids^{7,8}, and suggests that mitotic gene conversion may proceed by a mechanism which is different from that in meiosis.

These observations on duplications of the his4 locus apply to other regions of the yeast genome. Duplications of the leu2 gene, with the structure leu2-101 colE1 leu2-3 leu2-112, behave identically to the his4 duplications. About 95% of the LEU2+ recombinants are gene convertants. In a duplication with the structure LEU2+ ColE1 leu2-3 leu2-112, 17 Leu segregants were generated by a recombination event which separated leu2-3 from leu2-112. All these segregants retained the vector sequences (eight were leu2-112 ColE1 leu2-3 leu2-112 and nine were leu2-3 ColE1 leu2-3 leu2-112) (C. Styles and G. R. Fink, unpublished data). Thus, a high frequency of gene conversion occurs in prototrophic or auxotrophic recombinants as long as the event is intragenic.

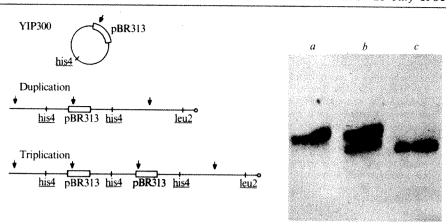

the event is intragenic.

Previous work²¹⁻²³ has shown that spontaneous and induced intragenic mitotic recombination can occur before DNA synthesis, at the two-strand stage. The reciprocal recombination which we observe in the duplication strains suggests that mitotic recombination is not restricted to one stage of the cell cycle. The fact that duplication strains in orientation II give rise to prototrophs which carry a triplication of the his4 region (Fig. 4) argues that, in a haploid, mitotic recombination can occur after DNA synthesis. This is the first evidence of sister-strand exchange in chromosomal regions outside the rDNA cistrons^{24,25}. It is unclear what proportion of the mitotic recombination events occur at this stage, because the other classes of recombinants could be produced either before DNA replication by an intrastrand recombination event or after DNA synthesis by an inter-strand event.

Gene conversion is decreased by rad52-1

The rad52-1 mutation has been reported to abolish meiotic recombination and to reduce mitotic recombination 12-14. We

Fig. 5 Quantitation of his4 regions. The diagram shows the configuration of the plasmid YIP300, a strain carrying a duplication of the his4 region and a strain carrying a triplication of this region. The thin line represents yeast DNA; the box represents pBR313 sequences and arrows represent SmaI endonuclease sites. Also shown is an autoradiogram of the hybridization profile of Smal-digested DNA from a a duplication: h a triplication and c, YIP300 using labelled plasmid as a probe. The two Smal fragments carrying pBR313 sequences in the duplication migrate together on an agarose gel. These two fragments are found in a triplication that has, in addition, a smaller Smal

fragment carrying pBR313 sequences which is the same size as the YIP300 plasmid. Nuclear DNA was isolated from the yeast strains by the method of Cryer et al. 46. Plasmid YIP300 was isolated as described by Hirt 47. After digestion with Smal the fragments were separated by agarose gel electrophoresis on a horizontal 0.5% agarose slab gel run at 100 V for 18 h. DNA was transferred to nitrocellulose filters 48 which were hybridized to a DNA probe 32p-labelled by nick translation 49. The probe was pBR322, a plasmid derived from pBR31350.

found that the rad52-1 mutation lowers the frequency of HIS4+ formation for his4 duplications of both orientations I and II. Further analysis of the HIS4⁺ recombinants produced in a rad 52-1 background indicate that gene conversion is affected preferentially. For orientation I, rad52-1 lowered the frequency of HIS4+ formation ~10-fold (Table 1). When HIS4+ recombinants were examined by colony hybridization using plasmid DNA as a probe, 186 (97%) had lost the pBR313 sequences (Table 2). In comparison, only 12% of the HIS4⁺ recombinants produced by the RAD52+ strains in orientation I had lost pBR313. The loss of the plasmid sequences indicates that a reciprocal recombination event had occurred (Fig. 4). When the overall frequency of HIS4+ formation in orientation I strains is separated into reciprocal recombination and gene conversion components, the component representing the reciprocal recombination frequency is essentially the same in the rad52-1 and RAD52+ backgrounds (Table 2). Thus, the 10-fold decrease in HIS4+ formation in rad52-1 strains is due to a greater than 200-fold decrease in gene conversion events.

The rad52-1 mutation lowered the frequency of HIS4+ formation in duplication strains of orientation II threefold. Colony hybridization using plasmid DNA as the probe showed that 145 (59%) of the HIS4+ recombinants had retained pBR313 and 101 (41%) had lost this sequence (Table 2). The proportion of His+ pBR313+ recombinants which were due to reciprocal recombination was determined by Southern hybridization analysis of whole yeast DNA from eight independent isolates (Fig. 5). This analysis showed that seven of the eight His+ pBR313+ recombinants carried a triplication of the his4 region, and therefore were a result of a reciprocal recombination event. The other His+ pBR313+ recombinant carried a duplication of the his4 region. As the eight strains are independent isolates, we assume that they are representative of the entire His⁺ pBR313⁺ population. On this assumption, 88% of the His+ pBR313+ and all the His+ pBR313 recombinants, or 93% of the total HIS4+ recombinants arising in a rad52-1, orientation II background are due to reciprocal recombination. When the overall frequency of HIS4⁺ formation is separated into reciprocal recombination and gene conversion components, the component representing the reciprocal recombination frequency is the same as that of the Rad52⁺, orientation II strain, and gene conversion has been decreased ~30-fold

There is a difference in the extent to which rad52 decreases the frequency of gene conversion in the strains of orientations I and II (Table 2). Others have reported that the effect of rad52 on mitotic recombination varies from 6- to 200-fold depending on the genetic interval studied $^{12-14}$. The differences we observed may be due to the orientation of the his4 alleles or to differences in the genetic backgrounds of the strains used here.

Studies on the effect of the rad52-1 mutation in diploid strains have shown that this allele affects mitosis and meiosis differently¹²⁻¹⁴. Meiotic recombination is completely abolished and mitotic recombination decreased. We have shown that in strains carrying the rad52-1 mutation the frequency of gene conversion not associated with reciprocal exchange is decreased dramatically, whereas the frequency of reciprocal recombinants is not affected (Table 2). The His⁺ prototrophs classed as reciprocal recombinants could be generated by gene conversion followed by reciprocal exchange. If this association of gene conversion with reciprocal recombination is frequent, then rad52 only affects mitotic gene conversion that is not associated with reciprocal exchange.

Discussion

We have shown that the major mitotic recombination event observed in duplications is gene conversion unassociated with reciprocal exchange. This result is consistent with the results of previous studies on mitotic recombination between single-copy genes in heteroallelic diploids^{7,8}. In addition, we observe that the rad52-1 mutation, which decreases mitotic exchange in diploids^{12,14}, preferentially decreases gene conversion in our system. These findings, taken together with earlier studies, suggest that gene conversion and reciprocal recombination occur by different pathways in mitosis.

Gene conversion between repeated DNA sequences may be involved in biologically important phenomena in yeast. For example, mating type interconversion is a complex event which seems to have some features in common with gene conversion within gene duplications^{26,27}. Mating type in yeast is controlled by two alleles of the MAT locus, MATa and MATa. Homothallic strains switch from one mating type to the other at a high frequency^{28,29}. This switching of mating type requires two other loci, HML and HMR³⁰⁻³². HML and HMR are unexpressed copies of the α and a information which can donate this information to the MAT locus^{33,34}. The replacement of MAT information by HML or HMR does not lead to a change at the donor locus. This aspect of homothallic switching is similar to gene conversion within duplications. One copy of the duplication acts as a donor of genetic information and the other as recipient. The donor sequences are not altered during the event. In contrast to mitotic gene conversion, mating type interconversion is a directed event; a information replaces MA $T\alpha$ and α information replaces MATa^{33,34}. Studies of cloned mating type genes show that the MAT, HML and HMR loci are direct repeats of common DNA sequences on chromosome III35,3 Thus, mating type loci are like the non-tandem direct repeats of the his4 gene which we have studied. Unlike the his4 gene duplications, where the two regions are completely homologous, each mating type locus contains one of two non-homologous

sequences (an 850-bp α-specific sequence or a 700-bp aspecific sequence) flanked by sequences homologous to all three loci³⁶. In spite of the differences between mating type interconversion and mitotic gene conversion, both involve the transfer of genetic information without rearrangement of the donor sequences. Moreover, the suggestion that the two processes occur by a similar event is supported by the finding that homothallic strains carrying the rad52-1 mutation are defective in mating type interconversion13.

Sequence homogeneity between highly repeated DNA sequences is thought to be maintained by mitotic recombination. In yeast, rDNA is composed of ~100 repeats of a 9-kb unit per haploid genome³⁷. Genetic and biochemical evidence suggests that the rDNA repeat units are tandemly arrayed, and within any individual strain these repeat units are homogeneous³⁸ Unequal sister-strand reciprocal recombination has been shown to occur in the rDNA cistrons in both mitosis and meiosis of

yeast^{24,25}. Szostak and Wu²⁵ propose that unequal sister-strand exchange occurs at a high enough frequency in mitotic cells to account for the homogeneity. Meiotic analysis of a duplication of the leu2 gene in yeast has led Klein and Petes 42 to suggest that gene conversion is a more likely mechanism for rDNA rectification. Our data indicate that mitotic gene conversion is far more frequent than unequal sister-strand exchange and therefore more likely to be responsible for sequence homogeneity. These conversion events could be responsible for the sequence homogeneity found in other types of repeated genes in eukaryotes, for example, the histone⁴³ and globin genes^{44,45}

We thank Tom Donahue, Forrest Chumley, Alan Hinnebusch and Cora Styles for critical reading of the manuscript and for helpful discussions. J.A.J. is a NIH predoctoral trainee on grant GM07617-02. Chromatin structure of endogenous retroviral genes and activation by an inhibitor of DNA methylation

Mark Groudine**, Robert Eisenman* & Harold Weintraub*

*Hutchinson Cancer Center, 1124 Columbia Street, Seattle, Washington 98104, USA †Department of Radiation Oncology, University of Washington Hospital, Seattle, Washington 98105, USA

The transcriptionally active ev-3 and inactive ev-1 endogenous retrovirus loci in chick cells differ in that ev-3 is undermethylated, preferentially sensitive to DNase I digestion, and contains nuclease hypersensitive sites in each of its two long terminal repeats. Transient exposure of cells to 5-azacytidine, a cytosine analogue which cannot be methylated at the 5 position, results in the hypomethylation and transcriptional activation of ev-1, as well as the acquisition of at least one nuclease-hypersensitive site within the chromosomal domain of ev-1.

ANALYSES from several laboratories have shown that expressed genes are packaged into an altered chromatin structure, as revealed by preferential DNase I digestion¹⁻⁴. These active regions are usually undermethylated at CpG dinucleotides 5-12. In many cases, gene activity is also correlated with a DNase I-hypersensitive site, which represents a very local alteration of chromatin that is associated with certain specific DNA sequences. These 'hypersensitive' regions are detected by the ability of DNase I to introduce double-stranded cuts at such

specific DNA sequences¹³. Thus, when nuclei are mildly digested with DNase I and the DNA isolated and redigested with restriction endonucleases, a sharp 'sub-band' appears on 'Southern' blotting. One end of this fragment is defined by the DNase I-generated double-stranded cuts in chromosomal DNA, and the other end by a neighbouring restriction site. Although many of the hypersensitive sites described thus far are very near the 5' border of transcriptionally active genes, others have been located in adjacent non-coding regions 14,15. The notion that hypersensitive sites may reflect important events in gene regulation is further supported by the finding that a change in location of these sites accompanies haemoglobin switching in the developing chicken embryo 14,16. Recently, we have shown that in precursor erythroblasts obtained from 22-h chick blastoderms, the globin genes are not transcribed; they are methylated, DNase I resistant and contain no hypersensitive sites. However, because all these parameters of gene activity become expressed coordinately (within the temporal resolution of our experiments) in progeny erythroblasts, it is not clear which, if any, of these structural features of active chromatin are primary and which secondary. We thus sought a system where we could experimentally manipulate such parameters.

In attempting to study the relationships between transcription, DNase I sensitivity, CpG methylation and hypersensitive sites, we have investigated these aspects of the endogenous avian retroviral genomes. Uninfected chicken cells contain one or more complete or nearly complete copies of genetically transmitted endogenous viruses, the prototype of which is called RAV-O. As described by Astrin¹⁷, most chickens contain at least one such genetic locus, ev-1, identifiable on 'Southern' blots as a 10.5-kilobase (kb) SsfI restriction fragment 18,19 Although ev-1 contains structural sequences nearly identical to RAV-O, it is basically silent in terms of expression²⁰. Astrin and co-workers21 have described at least 10 other avian genetic loci that contain structural genes for endogenous retroviruses, all of which are identifiable as specific Sst fragments. Of particular interest is ev-3, a deleted RAV-O locus which serves as the template for 31S and 22S viral RNA transcripts in uninfected chicken cells20,22. Although ev-3-containing cells do not produce either infectious virus or virus particles, they do contain a 120,000-molecular weight ev-3-coded polyprotein, P120Gs which represents an apparently non-functional, internally deleted form of the precursor to reverse transcriptase found in retrovirus infected cells 23,24 . The specific region of the ev-3deletion and detailed restriction maps of the various ev loci have been described recently 18,19,21,23,24

The present experiments demonstrate that, in contrast to ev-1, the conformation of ev-3 in chromatin results in sensitivity of this locus to digestion by DNase I and site-specific double-stranded cleavage at both the 5' and 3' ends of ev-3 (in long terminal repeat (LTR) sequence) by both DNase I and staphy-lococcal nuclease. In addition, and again in contrast to ev-1, several regions of ev-3 are undermethylated at cytosine residues at CpG dinucleotides. That undermethylation of at least some of these sites is important in permitting expression of the endogenous retroviral genome is strongly suggested by the transcriptional activation of an ev-1 locus by 5-azacytidine, a cytosine analogue which, due to a nitrogen substitution in the 5 position, cannot be methylated at this site²⁵. The activation of ev-1 by 5-azacytidine is also correlated with the generation of a

hypersensitive site within the chromosomal domain of this previously inactive retroviral genome. These results suggest that, at least for the ev-1 locus, undermethylation of at least part of the ev-1 locus results in the subsequent chromosomal activation of this genome as revealed by DNase sensitivity, transcription and synthesis of viral proteins.

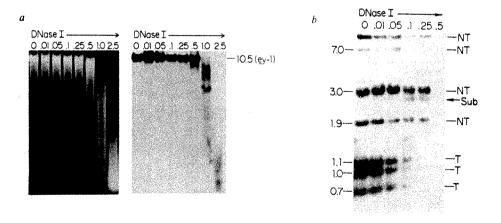

Preferential nuclease sensitivity of ev-3

Nuclei were isolated from red blood cells of 14-day chicken embryos characterized genotypically as either ev-1 or ev-1/ev-3. As previously reported 4.11.15, although such erythrocytes are no longer transcriptionally active, the globin genes previously expressed in these cells are preferentially sensitive to DNase I. The respective nuclear preparations were digested with very low levels of DNase I or staphylococcal nuclease 4.13.15 and the DNA was purified, restricted with Ssl, run on neutral 1% agarose gels, 'Southern' blotted and hybridized to 32P-RAV-O cDNA. (In all cases, identical results were obtained using cloned RAV-O sequence containing DNA as probe; however, we prefer to use the cDNA because it is usually higher in specific activity and gives much less background on blots.) Before restriction, most of this DNA had an average size of 15-20-kilobase pairs (kbp).

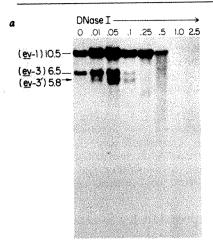

Figure 1 shows the results of DNase I digestion of nuclei from ev-1 red blood cells. As predicted from known restriction maps of ev-1 red blood cells. As predicted from known restriction maps of ev-1 red blood cells. As predicted from known restriction maps of ev-1 compared with bulk DNA, nor sub-bands indicative of site-specific double-stranded cuts within this locus are observed (Fig. 1a). Digestions with several other enzymes also fail to demonstrate sub-bands, indicating the lack of specific cuts in either the 5'- or 3'-flanking regions of this gene (not shown). As controls for the preferential digestion of active genes and generation of specific sub-bands in these DNA samples, restriction bands containing the α -globin genes once transcribed in these cells are no longer detectable in the sample digested with $0.25 \, \mu \mathrm{g} \, \mathrm{ml}^{-1}$ DNase I, and several samples show a specific sub-band containing globin flanking sequences (Fig. 1b).

Figure 2a reveals the results of a similar analysis performed with nuclei from cells containing both ev-1 and ev-3. In addition to confirming the relative 'insensitivity' of ev-1 to DNase I digestion, this figure demonstrates that ev-3 is much more sensitive to DNase I than is ev-1. Thus, the chromosomal conformation of ev-3 is similar to many transcriptionally active genes assayed by this technique. The kinetic analysis of the preferential digestion of the 6.5-kbp SsiI restriction fragment containing ev-3 also reveals a 5.8-kbp sub-band, indicating a site-specific double-stranded cut introduced into the chromosomal DNA in or around this locus. A similar sub-band is detected when nuclei from ev-1/ev-3 red cells are digested with increasing concentrations of staphylococcal nuclease (Fig. 2b), further indicating that a specific region of this endogenous viral locus is uniquely cut in the intact chromosome. Note,

Fig. 1 a, Resistance of ev-1 to low level DNase I digestion. Red blood cell nuclei from 14-day chicken embryos of ev-1 genotype were incubated with increasing amounts of DNase I at a DNA concentration of 1 mg ml-1 for 10 min at 37 °C. DNA was isolated, restricted with Ssd, electrophoresed on a neutral 1% agarose horizontal slab gel, stained with ethidium bromide. blotted on to a nitrocellulose filter and hybridized to ³²P-RAV-O cDNA. The dominant RAV-O related band in the Sst digest is 10.5 kbp, corresponding to ev-1. Numbers at the top of each lane refer to concentration (µg ml-1) of DNase I. b. Sensitivity of globin DNA to DNase I. The same DNA as shown in a was digested with Bam and EcoRI and hybridized to a genomic clone (α_s) containing transcribed (T) and nontranscribed (NT) regions of the chicken

 α -globin domain (the sub-band is generated from a hypersensitive site in a non-transcribed region of the α locus; see ref. 11 for details). The NT regions show a marked DNase sensitivity that has previously been shown to depend on HMG proteins, while the T regions show an 'intermediate' level of sensitivity that is not related to HMG binding. The ev-1 locus in a is classified as being DNase 'resistant'.

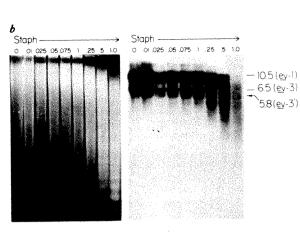

Fig. 2 Preferential sensitivity of ev-3 to DNase I and the generation of ev-3specific sub-bands by DNase I and staphyloccal nuclease. a, ev-1/ev-3 DNA was prepared and analysed after restriction with Sall as described for ev-1 DNA in Fig. 1. Two dominant RAV-O related bands in the Sst digest are the 10.5-kbp ev-1 and the 6.5-kbp ev-3. In addition to the preferential sensitivity of ev-3 to DNase I, a 5.8-kbp sub-band is revealed, b. DNA from staphylococcal nuclease-treased red blood cell nuclei from 14-day chicken embryos of ev-1/ev-3 genotype was prepared and analysed as above.

however, that the dramatic disappearance of ev-3 vis- \acute{a} -vis ev-1 seen in the DNase I digest (Fig. 2a) is not observed with staphycoccal nuclease digestion (Fig. 2b).

Previously, we reported the presence of RAV-O-related RNA and proteins in cells isolated from embryos of a particular flock of P120^{Gs}-negative, chick helper factor (chf) negative (gs chf), uninfected chickens²⁶. Using DNase I and solution hybridization we observed that these cells contained one 'active' and one 'inactive' retroviral genome. However, restriction mapping was not performed and the ev loci were not identified. Given the recent description by Astrin and co-workers²¹ of multiple ev loci associated with the gs chf phenotype, we reanalysed cells from this flock and observed that they contain both ev-1 and another 'phenotypically negative' ev locus, ev-8. Whereas ev-8 is DNase I sensitive in these cells, the ev-1 locus is resistant to DNase I, consistent with the above results. (A detailed analysis of these cells will be presented elsewhere.)

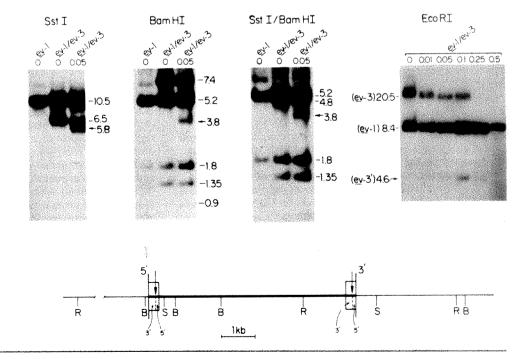

Mapping the hypersensitive site of ev-3

In an attempt to understand better the relationship between hypersensitive sites and gene activity, we mapped the region of ev-3 uniquely cut by DNase I and staphylococcal nuclease. Although all the mapping data presented here were generated from experiments with DNA from DNase I-digested nuclei, the same results are obtained with DNA samples from staphyloccal

nuclease-treated nuclei (not shown). Figure 3 shows the results of this analysis and a restriction map of ev-3. As indicated above (and in Fig. 3), a sub-band of 5.8 kbp is generated when the DNase I-treated samples are digested with Ssfl. Given the restriction map of ev-3, the hypersensitive site observed with Ssfl must be located either 700 bases 3' to the Sst site in the 5' end of the locus or within the LTR located on the 3' side of ev-3. When the same sample was digested with BamHI, a sub-band of 3.8 kbp was observed, indicating that the sub-band must be generated from a site within the 3' LTR. Ssfl/BamHI double digestion (Fig. 3) also shows a 3.8-kbp sub-band, providing further support for this conclusion. Given the location of Bam sites in the 5' end of the locus, this sub-band could only be generated by a DNase I-generated double-stranded cut in the 3' LTR.

As the LTR is repeated at both ends of ev-3, we wondered if a similar hypersensitive site was located in the LTR on the 5' side of the locus. Neither Sst nor Bam digestion would reveal such a site, because both cleave within the locus, 3' to the 5' LTR. We therefore hybridized an EcoRI-digested DNase series from ev-1/ev-3 cells with a ³²P-nick-translated DNA fragment containing sequences specific to the 'gag' gene located to the right of the 5' LTR. (The fragment was isolated from a pBR subclone provided by Drs W. DeLorbe and J.M. Bishop and their colleagues.) This probe detected the two expected EcoRIgenerated restriction fragments in the undigested sample

Fig. 3 Mapping the specific DNase Ihypersensitive Sites in ev-3. Th e restriction map of ev-3 is derived primarily from our own results, and the work of Hughes et al. 19. Undigested DNA from ev-1 and ev-1/ev-3 erythrocytes, and DNA from ev-1/ev-3 nuclei digested with 0.05 µg ml-1 DNase I were restricted with either Sstl or BamHI or doubly digested with Sstl and BamHI, and analysed as described in the previous figure legends. In addition, the DNase I-digested ev-1/ev-3 DNA 'series' presented in Fig. 2 was digested with EcoRI and analysed as above except that rather than using RAV-O cDNA, we used a ³²P-nick-translated DNA fragment containing sequences specific to the gag gene located to the right of the 5' LTR. In the EcoRI blot, the 20.5-kbp fragment is ev-3-specific, whereas the 8.4-kbp fragment is ev-1 specific. (In mapping the location of the nuclease-generated sub-bands with EcoRI, we have presented a kinetic analysis for optimal visualization of the ev-3 sub-bands.)

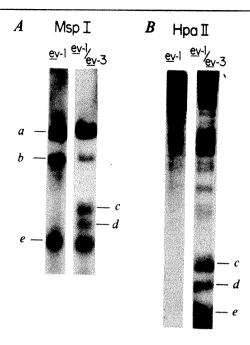

Fig. 4 Undermethylation of ev-3 relative to ev-1. DNA from ev-1 and ev-1/ev-3 erythrocytes was purified from nuclear preparations, digested with various restriction enzymes, electrophoresed on neutral, 1.4% agarose horizontal slab gels, blotted on to nitrocellulose and hybridized to 32 P-RAV-0 cDNA. A, MspI digestion of ev-1 and ev-3 DNA. B, HpaII digestion of the same samples. Note the generation by HpaII of fragments c, d and e in the ev-1/ev-3 cells, but not in ev-1 cells.

(20.5 kbp containing the 5' 5.0 kbp of ev-3 and 15.5 kbp of 5' flanking sequences, and an 8.4-kbp ev-1 specific fragment), but revealed a 4.6-kbp sub-band in the DNase I-digested samples (Fig. 3). As we have been unable to detect any retrovirus-related sub-bands in DNA from DNase-treated ev-1 nuclei using a variety of restriction enzymes and specific probes (Fig. 1 and other data not shown), the 4.6-kbp sub-band is probably generated from a hypersensitive site that maps in the 5' LTR of ev-3. This has been confirmed using several other probes and restriction enzymes, and we are now attempting to determine the exact sequence within the LTR that is cut by DNase I.

Thus, although no hypersensitive sites are observed in the ev-1 chromosomal domain, at least two such sites are apparent in ev-3, both located within regions of sequence homology (LTRs) on both the 5' and 3' side of the proviral coding regions. These LTR regions are of particular interest in terms of control of gene expression, given the sequence homology in this region to a number of putative control elements²⁷ (see discussion) and the ability of homologous regions in Rous sarcoma virus (RSV) to act as promoters in vitro²⁸.

Undermethylation of ev-3

Figure 4A and B show the results of restricting DNA from red cells of either ev-1 or ev-1/ev-3 genotype with Msp1 and HpaII, which recognize the sequence CCGG²⁹; however, Msp1 cuts at this site independent of the methylated state of the second C, whereas HpaII will not cut this sequence if the second C is methylated. As evident in Fig. 4A, ev-1/ev-3 DNA contains at least two more Msp1 restriction fragments (labelled c and d) than ev-1 DNA. Figure 4B illustrates that although ev-1 is highly methylated at CCGG sequences, the two ev-3-specific Msp1 fragments (c and d) are not methylated at such residues. In addition, several other regions are relatively undermethylated, given the generation of a broad band (e) of fragments with an average size of 300 base pairs (bp). We presume that these fragments come from ev-3 as they are not found in HpaII-digested DNA from ev-1 birds; however, we cannot formally rule out the possibility that under the influence of ev-3, these

fragments now become undermethylated at the ev-1 locus. We have also observed that whereas the 10.5-kbp SstI fragment characteristic of ev-1 is relatively stable on double digestion of ev-1 or ev-1/ev-3 DNA with SstI and HpaII, the 6.5-kbp SstI fragment characteristic of ev-3 disappears on Sst/HpaII double digestion of ev-1/ev-3 DNA (not shown). Thus, our results demonstrate qualitatively a clear correlation between the expressed ev-3 locus and undermethylation and an analogous correlation between the unexpressed ev-1 locus and hypermethylation. Although other investigators have also observed differences in the methylated state of retroviral genomes in various cells $^{30-32}$, correlation of expression and degree of methylation of a particular viral locus in these cells was not possible.

Induction of ev-1 expression by 5-azacytidine

In an attempt to understand the role of undermethylation in the control of gene activity, we analysed the effect of 5-azacytidine²⁵ on the expression of the inactive ev-1 locus. A continuous line of chicken lymphocytes containing only ev-1, MSB cells^{33,34}, was exposed to the cytosine analogue for 24 h (two or three generations), the medium containing the drug removed, fresh medium added and the cells assayed at various intervals for changes in ev-1 DNA methylation, RNA accumulation and virus-specific protein synthesis. DNA containing this analogue cannot be methylated at the substituted site²⁵. Moreover, during the 'chase' period most of the analogue is diluted out by replication. Thus, its effect on methylation occurs during the initial treatment, but the undermethylated state is nevertheless propagated to daughter cells independent of the continual presence of the analogue.

Figure 5A shows MspI and HpaII digestions of DNA from control and 5-azacytidine (AZA)-treated MSB cells. Although ev-1 MspI fragments are generally similar in red blood cells (Fig. 4) and MSB cells (Fig. 5), a small amount of what may be partial and limit restriction fragments is present in HpaII digests of MSB [for example, bands c and d in Fig. 5A (left)], but not erythrocyte DNA when blots containing restricted DNA from both cell types are exposed equivalently. As the MSB cells are routinely subcloned, these limit HpaII fragments may reflect the fidelity with which a particular methylation pattern is transmitted to daughter cells during DNA replication.

In contrast to the very small amount of signal observed in the limit restriction fragments from control MSB cells, exposure of these cells to azacytidine results in the genration by HpaII of the major MspI e fragments observed in control DNA. Based on the relative intensities of the e band observed in MspI and HpaII digests (Fig. 5A), within the limits of our assay, $\sim 50\%$ of the ev-1 Msp fragments in these cells are now undermethylated. We presume that this reflects the degree of substitution of 5-azacytidine during the initial treatment period.

To assay for gene expression, we isolated cytoplasmic RNA from control and azacytidine-treated MSB cells, 'dotted' the RNA on to nitocellulose35 and assayed for the appearance of RAV-O-related sequences by hybridization with ³²P-RAV-O cDNA (Fig. 5B). In these conditions we cannot detect significant signal from control cells, but signal from the AZA-MSB cells is observed as early as 24 h after removal of the analogue. Although the total amount of viral RNA increases between 24 and 48 h post-exposure, virus-specific RNA sequences change little between 48 and 72 h. To quantify ev-1-coded RNA sequences, we compared the intensities of the AZA-MSB RNA 'dots' with that from RNA isolated from chick embryo fibroblasts (CEF) infected with RSV, which by solution hybridization analysis contain ~5,000 copies of virus-specific RNA per cell (not shown). As the intensity of the 10 µg AZA-MSB 'dots' is comparable with that of the 0.1-µg RSV-CEF 'dots', we estimate that AZA-MSB cells contain ~50 copies of RAV-Orelated RNA per cell. This has also been confirmed by conventional hybridization analysis in solution. Obviously, this assay gives no information regarding the number of cells actually transcribing ev-1 (see below); however, here we are interested

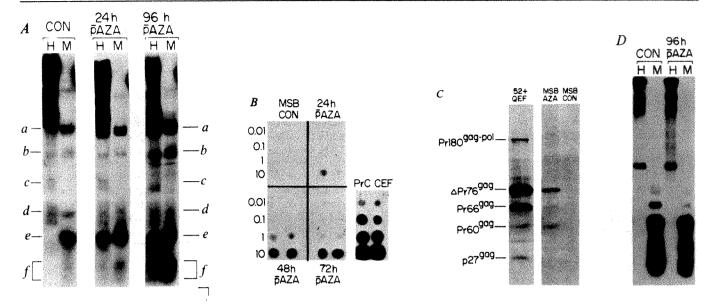

Fig. 5 Induction of ev-1 expression by 5-azacytidine. MSB cells were grown in media containing 3 μM 5-azacytidine (AZA) for 24 h, the analogue-containing medium was removed and the cells analysed 24, 48, 72 or 96 h after removal of the drug. A, Restriction of DNA from control (CON) and 5-azacytidine-treated (AZA) MSB cells with HpaII (H) and MspI (M) 24 and 96 h after removal of the analogue, and hybridization to ³²P-RAV-O cDNA. B, Dot blots' of cytoplasmic RNA isolated from control MSB cells, MSB cells at 24, 48 or 72 h after exposure to 5-azacytidine, and chick embryo fibroblasts (CEF) infected with RSV. 10, 1, 0.1 and 0.01 μg of each RNA sample were denatured at 65 °C, spotted in duplicate on to dry nitrocellulose filter paper (previously wetted with H₂O and soaked in 20 × SSC for 30 min), dried under a heat-lamp, and baked at 80 °C under vacuum for 2 h. The RNA-containing filters were prehybridized and then hybridized to ³²P-RAV-O cDNA. C, Analysis of retrovirus proteins in untreated or azacytidine-treated MSB cells. MSB cells were treated with 3 μM azacytidine for 24 h and allowed to grow for 3 additional days after removal of the drug. Untreated cells from the same culture were grown in parallel. The cells werewashed and incubated for 1 h at 37 °C with 200 μCi ³⁵S-methionine in methionine-deficient medium. Quail embryo fibroblasts (QEF) productively infected with the wild-type virus 52+ were similarly labelled. Cells were lysed as previously described^{23,24} and treated with 4 μl of a rabbit antiserum raised against purified retrovirus gag proteins and 80 μl of fixed Staphylococcus aureus. The immune complexes were washed extensively, dissolved in SDS (5%) electrophoresis sample buffer and subjected to electrophoresis on a 12.5% polyacrylamide slab gel; an autoradiograph of the dried gel is shown. The various gag-related polypeptides immunoprecipitated with the antiserum represent the different cleavage proteins generated from the primary precursor, Pr76²⁸C. D, Hybridization of a ³²P-nick tra

in any transcription of the retroviral locus in the AZA-cells compared with control MSB cells. Interestingly, analysis of viral RNA content in cells containing the active endogenous ev-3 genome has revealed that such cells also contain ~ 50 copies of RAV-O-related RNA per cell²².

We also investigated the synthesis of viral proteins in the 5-azacytidine-treated cells. MSB cells have been characterized as negative for endogenous retroviral gag, pol and env gene expression³⁶ and, as shown in Fig. 5C, we could not detect any of the viral internal structural proteins (gag) in the control MSB cells. However, Fig. 5C also shows that the gag precursor polyprotein Pr76gag and two of its cleavage intermediates, Pr66 and Pr60, are detectable in MSB cells assayed 72 h after exposure to azacytidine. Of significance, viral particles are also detectable in the supernatant medium from these cells, but they do not contain reverse transcriptase (R. Eisenman and K. Conklin, unpublished observations). The absence of reverse transcriptase actually facilitates our assay, for the particles are thus uninfectious, and our results cannot be attributed to reinfection of the AZA-MSB cells by RAV-O. (A detailed characterization of the viral RNA, protein and particles is in preparation.)

As expected from the results of Jones and Taylor²⁵, our results depend on incorporation of the analogue into cellular DNA; concurrent exposure of MSB cells to azacytidine and inhibition of DNA synthesis by cytosine arabinoside or hydroxyurea results in none of the observed changes in DNA methylation or viral RNA accumulation (not shown). We have also observed that 24 h exposure of MSB cells to concentrations of azacytidine $>7 \,\mu$ M results in severe toxicity, with only 10–20% of the cells remaining viable 48 h after its removal. At the concentration used in these experiments (3 μ M), a minimum of 50% of the cells are viable when assayed at 48 h post 'wash-out'. We have also observed ev-1 activation on 8 h exposure of MSB cells to 1 μ M azacytidine and, in these conditions, >90% of the cells remain viable. Finally, we have observed similar changes in ev-1

DNA methylation, RNA accumulation and protein synthesis on exposure of cultures of ev-1 containing chick embryo fibroblasts to the analogue (unpublished observations). Thus, azacytidine is effective both in activating whole programmes of differentiation in mouse cells²⁵ (see discussion) and in activating a particular gene in chicken cells, in a continuous line and in primary fibroblasts.

In contrast to the 5-azacytidine-induced undermethylation of regions of ev-1, we have observed no significant changes in the methylated state of five different α - and β -globin genes in these same 5-azacytidine-treated MSB cells. For example, using an embryonic β -globin probe and the same MSB AZA-DNA described above, none of the globin-specific MspI-generated fragments is observed with HpaII digestion (Fig. 5D). The methylated state of these various globin genes has been maintained in every MSB AZA-DNA sample tested. Thus, the undermethylated state resulting from 5-azacytidine treatment is apparently non-random (see discussion).

An ev-1 hypersensitive site induced by 5-azacytidine

As mentioned above, regions of DNase I hypersensitivity have been described for several transcriptionally active genes $^{7,13-15,37}$. Although HMG 14 and 17 are responsible, at least in part, for the preferential sensitivity of each nucleosome within a particular transcription unit 38 , the basis of the hypersensitivity of the particular point site is unclear (see ref. 39 for extensive discussion). Using β -globin genes, we demonstrated previously that the appearance of these sites coincides with the developmental activation of any one particular β -globin gene. Thus, although no β -globin-hypersensitive sites are observed in precursor haematocytoblasts, such sites are detectable near the embryonic β -globin genes in daughter, first generation erythroblasts 16 . The generation of hypersensitive sites during development suggests that these regions are not 'stable' areas in

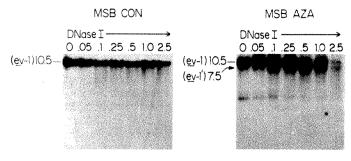

Fig. 6 Appearance of a DNase I-hypersensitive site after treatment of MSB cells with 5-azacytidine. Nuclei from control MSB cells and MSB cells 72 h after exposure to 5-azacytidine were incubated with increasing amounts of DNase I and analysed as described for red blood cell nuclei in Fig. 1. Although no sub-band is detectable in the control cells, a prominent 7.5-kbp sub-band (in addition to the expected 10.5-kbp ev-1 SsI fragment) is observed in these cells after exposure to the cytosine analogue.

terms of chromosomal conformation, but are the results of processes involved in the developmental activation of particular regions of the chromosome. We wondered, therefore, whether the transcriptional activation of ev-1 by 5-azacytidine was also correlated with the generation of a hypersensitive site within the chromosomal domain of this retroviral genome. Figure 6 shows the results of low-level DNase I digestions of control and azacytidine-treated MSB cells. Whereas no ev-1-related subbands are detectable in the SstI-restricted DNA from control cells, a prominent 7.5-kbp sub-band is observed in the DNA isolated from DNase I-digested nuclei of MSB cells, analysed 72 h after exposure to the analogue. In addition, the intensity of the sub-band and the kinetics of its disappearance compared with those of the 10.5-kbp ev-1 SstI fragment, indicate that the hypersensitive site is present in $\sim 50\%$ of the cells in the azacytidine-treated population. Thus, the activation of ev-1 by 5-azacytidine is associated with a change in the chromosomal conformation of this gene, paralleling the developmental activation of the chicken globin genes.

Extensive mapping of the azacytidine-induced ev-1 sub-band (similar to that described in mapping the ev-3 sub-band) has revealed site-specific double-stranded cuts in both the 3' and 5' LTRs of the endogenous retrovirus (unpublished observations), suggesting that transcriptional activity of two distinct endogenous retroviral loci is associated with a conformational change at a specific sequence located at both ends of these genomes.

Discussion

The experiments described above reveal that the expression of retroviral genomes, like many genes, is correlated with the conformation of these sequences in chromatin. Thus, the unexpressed ev-1 locus is no more sensitive to DNase I than bulk DNA, whereas the transcriptionally active ev-3 locus is preferentially sensitive to DNase digestion. In addition, and again as in several other systems, the unexpressed ev-1 is highly methylated at CCGG residues, whereas the 'active' ev-3 is relatively undermethylated at these sites. Similarly, although no hypersensitive site is observed on low level DNase digestion of ev-1, two hypersensitive sites are detectable (with both DNase I and staphylococcal nuclease) in ev-3. These sites are located within the LTR on either side of this retroviral genome. As described by Ju and Skalka²⁷, the LTRs of many retroviruses contain regions of homology with several other genetic elements. Particularly intriguing is a 15/20-bp sequence homology between the retroviral LTRs (CGTCATTCG'ACGATAG-TAG) and a tandemly repeated region in SV40 (CGT**TTCGTACG*TAG*AG), in which this sequence is present in a location recently described as essential for the initiation in vivo of early transcription⁴⁰. In addition, this same region of SV40 contains a DNase I-hypersensitive site associated with early transcription (C. Cremisi, unpublished observation) and is part of a larger region that is preferentially exposed to staphylococcal nuclease and various restriction endonucleases late in infection^{41,42}. The ev-3 sub-band mapping data presented above tend to localize the ev-3-hypersensitive sites to the border of the 5' and 3' sequences within the LTR (see Fig. 3); however, the error in this analysis is such $(\pm 100 \text{ bp})$ that the hypersensitive site could be located in the region of the LTR containing sequence homology with SV40. Several other sequences important in transcriptional control—a TATAA box and a cap site—are also located within this 200-bp region of the LTR. Given the location of such sites in both LTRs, we believe that a particular DNA sequence or sequences dictates the chromosomal conformation revealed by the DNase I-hypersensitive sites. Clearly, other factors (such as the pattern of DNA methylation) are also important because in normal chicken cells the LTRs present in ev-1 are not hypersensitive even though they contain sequences with the potential for generating hypersensitive regions, as evidenced by the appearance of such sites after treatment with azacytidine. Recently, Blair et al.43 have shown that ligation of LTRs to either the 5' or the 3' side of a virus-transforming gene increased the frequency of morphologically transformed colonies after DNA transfection. In the context of the present experiments, these results suggest that LTRs increase transcription not only by providing a highefficiency 'promoter'44, but also by 'opening-up' large tracts or domains of chromatin structure, possibly by phasing adjacent nucleosomes or segregating genes into a specific nuclear compartment required for transcription. If this is so, and if the LTR signal for this proposed change in chromatin structure is bidirectional (as its many inverted repeats suggest), it would not be surprising if these sequences have an effect when placed either 5' or 3' to a given gene. Although the biochemical basis for the hypersensitivity is unknown, these sites may represent regions of specific interactions with DNA sequence recognizing proteins. DNA 'footprinting' analysis of several DNA binding proteins has shown that sites within the binding domain of the protein can be 10-100-fold more sensitive to DNase I cutting when the protein is bound⁴⁵

We have also demonstrated that 5-azacytidine-induced undermethylation of the unexpressed ev-1 results in the transcriptional activation of this retroviral genome. In contrast to the induction of murine proviruses by such agents as BUdR and IUdR, induction of ev-1 in chickens by halogenated pyrimidines or other agents has not been demonstrated. However, several experiments 46,47, and our preliminary results, indicate that ev-1 cannot be efficiently induced by such agents. Although our azacytidine results strongly suggest that ev-1 activation is effected through a change in the methylated state of DNA, this has not been proved (for example, by DNA-mediated transfer). However, it is supported by the evidence presented above (change in cutting at HpaII sites; requirement for DNA synthesis; and generation of hypersensitive sites) and by the findings that ethionine and 3-deazaadenosine, two very different types of analogues which affect DNA methylation, also induce gene activity 48,49. Nevertheless, at present there is no direct experiment to exclude the possiblity that azacytidine leads to the activation of some other cellular locus which, in turn, activates the ev-1 locus. In this regard, results of transfection experiments in murine cells indicate that halogenated pyrimidines can affect viral gene transcription by acting at a site other than the viral genome⁵⁰. Our inability to observe 5-azacytidine-induced changes in the methylated state of several globin genes in the same cells in which regions of ev-1 are clearly undermethylated could be interpreted to support such a trans effect, assuming that the 'target size' for the putative regulating locus of ev-1 is much larger than that for the entire globin domain. Alternatively, it seems more reasonable that initially all genes are equivalently undermethylated, but that some type of selective correction mechanism leads to the re-methylation of the globin genes. Finally, the observed selective undermethylation of ev-1 in the AZA-MSB cells could be due to a non-random incorporation of the analogue. All these possibilities are being investigated.

The role of DNA methylation and gene function has been studied by several laboratories and recently reviewed by Razin and Riggs⁵¹. Our own work focuses on a particular gene and also suggests that undermethylation is important in generating a chromosomal structure permissive for transcription, for the transcriptional activation of ev-1 accompanies the appearance of a hypersensitive site, similar in location to that point site associated with the transcriptionally active ev-3. Our experiments seem to suggest that undermethylaton of all or a specific subset of CpG dinucleotide sites within the chromosomal domain of a given gene precedes the acquisition in chromatin by that gene of a conformational change permissive for transcription. It seems useful to compare our results on the activation of ev-1 with those of Jones and Taylor, who monitored cytodifferentiation, the presumed activation of entire programmes for gene activity. Using roughly comparable degrees of exposure to azacytidine, we estimate that at least 50% of the ev-1 loci are activated (see above), whereas Jones and Taylor observed about 1% of the cells in their cultures differentiating, for example, into muscle cells. We presume that the differences in frequency reflect the relative sizes of the respective targets needed to be substituted for the two assays. This could

represent a requirement for greater substitution in a single target for myogenesis or, more likely, a requirement to activate more genes before muscle cytodifferentiation can be

Although the examples of chicken α - and β -globin genes^{5,11} and the active retroviral genomes described above, show a striking correlation between gene expression and hypomethylation of almost all the HpaII sites in a transcription unit, most studies in other systems do not support such a simple correlation (for example, ref. 10). Thus, we feel that undermethylation of specific regions of a locus^{6,9,10} may be the signal important in generating an active chromatin structure. This hypothesis predicts that exposure of MSB cells to very low levels of 5azacytidine should result in the transcriptional activation of ev-1in a subpopulation of the cells undermethylated only at one site or a few sites, possibly within the LTR. Analysis of subclones of such cells would then be expected also to reveal a specific hypersensitive site.

The Red Rectangle¹ is a nebula centred on the star HD44179. Within an amorphous blue nebula is embedded a hollow biconical red nebula with apex at the star. The generators of the hollow bicone show in projection as four spikes radiating from HD44179. The bicone has a hitherto totally unidentified spectrum. In high resolution spectra of the nebula we have identified a narrow-line component (Na D, Ca H and K, Hα) from a low excitation plasma and we have resolved broader features presumably from molecular bands. Here we give constraints on the molecules responsible, and propose as a candidate carbyne (linear chains of carbon with alternate single and triple bonds). The Red Rectangle may thus be a factory for the production of the raw material from which some interstellar molecules are made.

Low resolution (50 Å) spectra² of the Red Rectangle show a blue continuum spectrum identical to that of the central star, plus a broad red emission feature which extends over 2,100 Å and is centred near 6,400 Å. From polarization measurements3.4 it is clear that, while the blue spectrum is scattered star light from HD44179, the red spectrum is emission originating on the bicone. Polarization studies indicate4 that the bicone is formed of a concentration of dust grains as well as the unknown ingredient X_{RR} responsible for the red emission feature. Moderate resolution spectra (10 Å) break³ the feature into considerable structure, including resolved components grouped like molecular band-heads, presumably from a molecule X_{RR} in association with the dust grains which give the polarization behaviour. IR spectra^{1,5} of HD44179 itself show emission bands also usually seen in association with dust, but not the 9.7-µm feature which is a signature of silicates.

We have taken high resolution (1 Å) spectra of the Red Rectangle on the 3.9-m Anglo-Australian Telescope in several positions in the nebula, and spectra of the central star, in the wavelength range $\lambda 3,400-6,600$. Figure 1 illustrates the spatially summed spectrum of the nebula in the wavelength range λ 5,700-6,660, which includes most of the red emission feature. Figure 2 illustrates the blue spectrum 3,400-4,400 Å which shows prominently the Balmer absorption lines in the reflection spectrum.

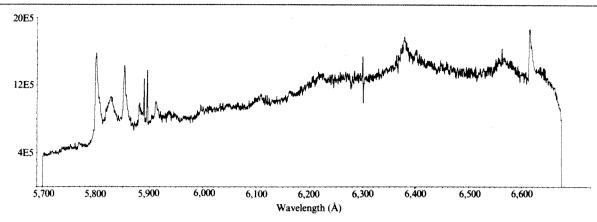

Fig. 1 Spectrum of section 1.2 arc s wide across the nebula, centred 7 arc s north of HD44179 at position angle 120°, as observed for 10,000 s with 0.5 Å spectral elements. Ordinate represents photons detectable per element in a perfectly efficient 3.9-m telescope. The D lines and H α are superimposed on a banded spectrum. (The feature at 6,300 Å is from night-sky emission.)

In these spectra of the nebulosity there are four distinct types of emission features superimposed on the scattered stellar continuum:

(1) The nebula contains narrow emission lines at the wavelengths Na D (strong), Hα (weak), and Ca II H and K (strong). The central star has strong narrow emission lines of Na D and strong H α emission, but no detectable H and K emission; on the contrary, there is weak K-line absorption, perhaps interstellar. Thus these nebular emission lines are not scattered starlight but are intrinsic emission from the nebula. Indeed, the ratio of the Na D lines varies across the nebula, being $\sim 2:1$ (optically thin) just outside and within the bicone but $\sim 1:1$ (optically thick) on the spikes, thus confirming the hollow structure of the bicone. There is no detectable broadening or splitting or velocity shift of the sodium lines across the nebula, and we estimate that projected bulk motions in this plasma are less than 15 km s⁻¹, and turbulent motion has a FWHM less than 35 km s⁻¹. The narrow emission lines are from a very low excitation plasma. The ionization potentials of Na I and Ca II are 5.1 and 11.9 eV; the weak H α indicates that ionization energies just up to 13.6 eV are available. The mean surface brightness of $H\alpha$ over the part of the nebula which we measured is 6.9×10^5 photons s⁻¹ sr⁻¹ cm⁻² which is consistent with ionization by the AO-B8 II-III star HD44179 (Strömgren sphere of 1-2 pc diameter) of $3-8 \times 10^{-6}$ solar masses of hydrogen (distance¹ of 330 pc, angular size = 0.5 arc min FWHM) with r.m.s. density in the range $40-100 \text{ cm}^{-3}$. The H α detection is consistent with upper limits to radio detection¹ at 8.4 and 15 GHz of ~ 0.05 Jy. The low excitation spectrum of the nebula indicates that its temperature is lower than the canonical 104K of a typical H II region. Other low temperature H II regions⁶, which may be cooled by abundance anomalies⁷ (metal rich), have temperatures in the region of 4,000 K, and judging by its low ionization, the Red Rectangle may be cooler still.

The other three types of feature in the spectrum of the Red Rectangle are difficult to identify.

- (2) There is the very broad feature, which ranges³ from $\lambda 5,400$ to 7,500.
- (3) There are R-type band-like features characterized by a sharp rise from the shorter wavelength and a gradual degradation to the red⁸; these occur at λ 5,799, 5,855, 5,880 and 6,615, the first two and the last one being most prominent. All these features have very similar structure and their relative intensities remain reasonably constant with position in the nebula. However, the degree of degradation to the red seems to decrease on the spikes at the edge of the biconical nebula. No velocity structure, as measured by the peak of the R-type features, can be seen over the nebula, to an accuracy of 50 km s⁻¹.
- (4) The emission from the Red Rectangle also contains M-type diffuse features that are broad (10-20 Å FWHM), peaked in the middle and centred at $\lambda 5,828$, 5,913, 5,938, 6,109, 6,208, 6,378, 6,420, 6,563. There may be weak features in the blue spectrum but because of low signal-to-noise and confusion with the Balmer series we cannot identify them well; we note the possible feature at 4,044-4,053.

The ingredient X_{RR} which gives rise to all these features may be simple molecules trapped on the grains abundant within the nebula, in which case the mode of attachment may modify the emission wavelengths and a comparison with laboratory spectra of 'free' molecules would not yield an identification. Alternatively the emission may be from the grains themselves undergoing a form of fluorescence as a result of some illumination from the central star, although no outstanding stellar spec-

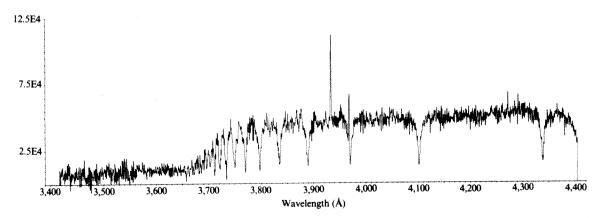

Fig. 2 Spectrum of the blue region of the nebular spectrum showing H and K emission superimposéd on the Balmer line continuum of scattered star light. Ordinate as Fig. 1, for 2,000 s integration.

tral component for this illumination can be identified. It is more likely³ that ingredient X_{RR} consists of free molecules in the nebular medium.

If the features are molecular emission lines³ then the very broad emission feature (2) could correspond to molecular dissociation, and features (3) and (4) could be transitions between vibrational states of different electronic states of the molecule. The diffuse or degraded structure could correspond to rotational broadening, and changes in the degradation from place to place correspond to a difference in excitation temperature. The question arises as to which molecule X_{RR} might be.

There are some coincidences³ between the spectrum of the Red Rectangle and that of H₂O⁺ (as found in comets⁹) and of C₃ but in each case there are additional spectral lines of these molecules that are absent from the spectra. The C₃ series is the better fit because in the laboratory it produces phosphorescent lines at 5,856, 5,874, 5,911, 5,969 and 6,308 Å in a neon trapping gas, with a 50-Å shift to the red in argon¹⁰. A 57-Å shift to the blue (in an arbitrary attempt to simulate the environment in the Red Rectangle) produces 5,799, 5,817, 5,854, 5,912 and 6,251 Å which may be identified with the X_{RR} transitions at 5,799, 5,828?, 5,855, 5,912 and 6,208?? Å but does not identify the third strongest band at 6,615. It is tempting to identify the weak blue feature at 4,050 Å with the strongest of the Swings' band of C₃, and this would indicate that there may be limited regions in the Red Rectangle with temperature ≤3,000 K.

There is, however, a general similarity between the spectrum of the Red Rectangle and those of some open-shell organic cations studied by Maier¹¹. They have a broad (~2,000 Å) dissociation spectrum in the red (5,000-8,000 Å region for the examples given) and red degraded or middle-peaked bands which are strongest on the blue end of the broad feature. Common building blocks of many of these linear organic molecules are the C≡C and C-C bonds. Maier¹¹ gives the vibrational frequencies of the stretching fundamentals of the C≡C and C-C bonds as 2,119 and 629 cm⁻¹ for the ground molecular state of dicyanoacetylene. These frequencies are not significantly different (±20%) for the same bonds in other linear cations quoted by him or for the neutral molecules which we anticipate will be present in the Red Rectangle. It so happens that in the Red Rectangle spectrum the stronger bands at λ 5,799 and λ 6,615 have an energy difference of 2,127 cm⁻¹ and the bands at $\lambda 5,880$ and $\lambda 6,109$ have a difference of 638 cm⁻¹. As both these energy differences in X_{RR} correspond well with those of the C≡C and C-C bond stretching frequencies, it is tempting to identify X_{RR} with an unknown linear organic molecule that is constituted in part by C≡C and C-C configurations. Linear carbon chain molecules have low transverse vibrational frequencies and these may also contribute in addition to rotational effects to the detailed structure of the observed band-like features.

Many of the organic molecules found in the interstellar medium contain some such configurations, for example cyanoacetylene^{12,13} $(H-C\equiv C-C\equiv N)$. Carbyne, which has been proposed14 as a constituent of interstellar material, is a linear structure of carbon with strings of C−C≡C chains. Webster 14 attributes some of the unidentified IR bands between 3.27 and 11.3 µm to carbyne; they are carried by something that is carbon-rich^{15,16} and are present⁵ in HD44179. Carbyne is stable 17 between 2,600 K and 3,800 K, consistent with the temperature of the narrow-line plasma in which the bicone is bathed. Carbyne might be produced¹⁷ above ~3,000K from C₃ molecules (C=C=C) by transfer of one bond and/or from graphite grains by fracturing the hexagonal planes of which graphite is composed. We have pointed already to the marginal evidence for the 4,050 Swings' C₃ band in the Red Rectangle and to the absence of the 9.7-µm feature in the grains in HD44179 so that in the absence of silicate grains 15,16 we therefore suppose they may be graphite in an oxygen-deficient environment. It is thus conceivable that carbon phases associated with carbyne are present in the Red Rectangle, and it is a likely candidate for X_{RR} although in the absence of a reference

spectrum the case is circumstantial. We cannot exclude other molecules as we have no explanations for several features in the spectra.

The formation of a linear molecule such as carbyne in the nebular environment around stars like the Red Rectangle may be an important initial step in the production of the many organic molecules found in the interstellar medium.

We thank D. T. Clark, G. D. Rochester and Sue Worswick for help with the molecular spectroscopy.

Inverse comptonization and the nature of the March 1979 γ -ray burst event

E. P. T. Liang

Institute for Plasma Research, Stanford University, Stanford, California 94305, USA, and Lawrence Livermore National Laboratory, University of California, Livermore, California 94550, USA

The central issue concerning the nature of the 5 March 1979 γ -ray burst is that of whether its source is the supernova remnant N49 in the Large Magellanic Cloud (LMC), whose extragalactic distance implies unusually high (super-Eddington) luminosity. Although the optically thin synchrotron mechanism proposed by Ramaty et al.1 has met many of the earlier theoretical objections, other evidence is needed to support or disprove such an extragalactic origin. I point out here that the observed burst spectrum seems to be most naturally and consistently interpreted as that of a synchrotron spectrum modified by inverse from ~MeV e*-pairs. scattering Comptonization describes the gain of energy by photons as a result of scattering with electrons of much higher energy.) This model then allows us to derive, from first principles, the intrinsic synchrotron luminosity of the burst source, which agrees basically with that expected from N49 (distance ~55 kpc).

The model spectrum of Ramaty et al. suggests that the spectral density above ~400 keV is greater than that from a simple redshifted pair annihilation line (Fig. 1). On the other hand, a power-law tail with a high energy cutoff (at 1.5-2 MeV in the present case, Fig. 1) is produced when a copious supply of soft photons (the synchrotron X rays below ~300 keV in the present case) is made more energetic by Compton scattering from hot electrons, provided that the Comptonization is unsaturated (the average fractional energy gain of the emerging photons = $y \le 1$)³⁻⁵. This has become the normal interpretation of the X-ray spectra of Cyg X-1 and of active galaxies. It is evident that the same relativistic pairs that are emitting the synchrotron X rays in the model of Ramaty et al. would automatically also Compton upscatter some of them, despite the low scattering depth. Hence, the dominant contribution to the y intensity above the break at ~300 keV (Fig. 1) is taken here to be comptonized photons, with only a small admixture of redshifted 511-keV photons producing the bump at 430 keV

(ref. 2). Uncertainty in the annihilation photon contribution does not matter in our estimates as long as it is smaller than the continuum. But, to be specific, the Compton continuum is taken as that lying below the dashed line in Fig. 1, with the excess due to the line contribution. The dashed line is the best fit to the data based on the general form of the unsaturated inverse Compton spectrum^{3.6} (see below).

In the limit when comptonization is highly unsaturated ($y = \text{Kompaneet parameter} \ll 1$)³⁻⁵, which is evidently the case here, the ratio of the hard comptonized energy flux F_{C} to the uncomptonized soft flux F_{S} is simply $F_{\text{C}}/F_{\text{S}} \approx y$ (refs 3, 5). Breaking the spectrum at $\sim 300 \text{ keV}$ (Fig. 1: S denotes synchrotron component; C, Compton component) we find

$$y \cong \frac{F_{\rm C}}{F_{\rm s}} \simeq 0.077 \tag{1}$$

Also, in the optically thin limit $(\tau_{es} \ll 1)$, the ratio of comptonized photons N_C to uncomptonized photons N_S is the mean scattering probability:

$$\tau_{\rm es} \cong \frac{N_{\rm C}}{N_{\rm c}} \cong 6.5 \times 10^{-3} \tag{2}$$

(from Fig. 1). In the relativistic regime^{7.8},

$$y = \frac{4}{3}\tau_{\rm es}\Gamma^2$$

where $\Gamma \equiv \bar{E}/m_e c^2$ is the average relativistic factor of the pairs. Hence,

$$\Gamma^2 \cong 8.9 \quad \text{or} \quad \Gamma \cong 3$$
 (3)

This is consistent with the apparent steepening of the tail above ~ 1 MeV. Pozdnyakov *et al.*⁶ have derived the spectral index of the power law tail for relativistic comptonization. The effective spectral index in the present case is⁶

$$\alpha = -\frac{\ln \tau_{\rm es}}{\ln (4\Gamma^2/3)} \approx 2.04 \tag{4}$$

using equations (2) and (3). Hence, the predicted photon number spectrum is in approximate agreement with the dashed curve (ref. 6, Fig. 4).

From equation (2), we find the pair column density

$$n_e h = (n_+ + n_-)h = \frac{\tau_{es}}{\sigma_{KN}} = 3.42 \times 10^{22} \text{ cm}^{-2}$$
 (5)

where the Klein-Nishina cross-section $\sigma_{\rm KN} \approx 1.9 \times 10^{25} \, {\rm cm}^2$ at $\Gamma \approx 3$. The soft component is essentially an exponential of decay constant $\sim \! 20$ to $30 \, {\rm keV}$. Interpreting this as the (redshifted) critical synchrotron frequency.^{7,8}, we have

$$h\nu_c \equiv 1.78 \times 10^{-11} B_{Gauss} \Gamma^2 \text{ keV}$$

 $\approx 30 \text{ keV}$ (6)

Hence,

$$B \simeq 1.9 \times 10^{11} \,\mathrm{G} \tag{7}$$

consistent with the field expected at a typical neutron star surface. From equation (5) and (7), we derive the intrinsic synchrotron luminosity

$$L_{\text{syn}} = 2.3 \times 10^{-2} B^2 \Gamma^2 n_{\text{e}} h f_{*}$$

= $f_{*} 2.5 \times 10^{44} \text{ erg s}^{-1}$ (8)

where f_* is the fraction of the surface area of a 15-km neutron star that is emitting. This (optically thin) synchrotron luminosity, which is derived without any reference to the assumed distance to the source, is so close to the quoted burst luminosity of $\sim 3 \times 10^{44} \, {\rm erg \, s^{-1}}$ at the distance of N49 that it serves as a consistency check on the LMC identification (f_* is expected to be of the order unity from the width of the subsequent 8-s period pulses²). The mean synchrotron self-absorption depth is $\bar{\tau}_{\rm syn} \sim 10^{-4}$, completely justifying the optically thin assumption (used in equation (8)). In fact, the frequency at which the self-absorption depth approaches 1 is $\sim 20 \, {\rm keV}$, consistent with the obser-

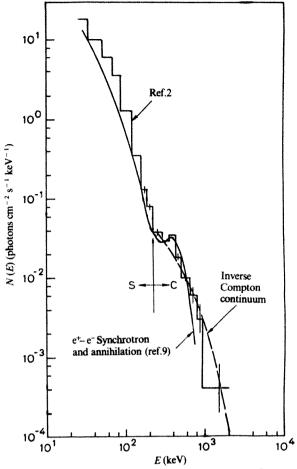

Fig. 1 Comparison of the models of the 5 March 1979 γ -ray transient, according to Mazets² and Ramaty *et al.*⁹ with the present inverse Compton continuum.

ved low-energy turnover. The synchrotron cooling time of the relativistic pairs is

$$t_{\text{syn cool}} \simeq \frac{6 \times 10^8 \,\text{s}}{R^2 \Gamma} \simeq 2 \times 10^{-15} \,\text{s}$$
 (9)

much shorter than bremsstralung cooling time or pair annihilation time. Hence, the pairs cool before annihilation, as expected. However, their probability of Compton-upscattering soft photons before cooling down is still high because of the large amount of soft photons present:

$$t_{\rm es} = \frac{1}{n_{\gamma}\sigma_{\rm KN}c} \sim 3 \times 10^{-15} \quad \rm s$$

Equation (9) also indicates that the long duration of the burst (\sim 120 ms) must be supported by a continuous supply of relativistic pairs which may be produced from slow dissipation of large energy reserves (for example, neutron star vibrations of ref. 9).

If we identify all the excess above the dashed line continuum in Fig. 1 as coming from pair annihilation, we find (now assuming a true distance of 55 kpc) for the pair annihilation tuminosity

$$L \approx 1.8 \times 10^{41} \text{ erg s}^{-1}$$
 (10)

or

$$n_+ n_- h f_* \approx 1.4 \times 10^{48}$$
 (11)

Assuming $n_{+} \approx n_{-}$, we have, combining equations (11) and (5),

$$n_{+} \simeq 10^{26} f_{*}^{-1} \text{ cm}^{-3}$$

and

$$h \approx 2 \times 10^{-4} f_* \text{ cm}$$
 (12)

These numbers are generally similar to those of Ramaty et al.¹ One clue as to why h is so small may be the extremely short

cooling time of the relativistic pairs which limits the distance over which a newly created pair can traverse before cooling down ($ct_{\rm syn\,cool} \simeq 6 \times 10^{-5}$ cm). Of course, we still need to explain why all pairs must be created in such a thin layer. As with all models dealing with an LMC origin, this model still faces problems related to the huge energy source, fast coupling, and the slow decay of the subsequent pulsations. Of course, interesting ideas have already been proposed (see ref. 9), but detailed analysis remains to be done.

I thank Vahe Petrosian and Spiro Antiochos for detailed discussions and Rueven Ramaty for comments. Lorna Campbell first drew my attention to this event. I also thank Tom Cline for communicating the latest refinement of the position determination, which puts the y-source definitely inside N49 X ray contours but not at the centre 10.

This research was partially supported by NASA grants NAS

Microanalysis by Raman spectroscopy of carbon in the Tieschitz chondrite

Mireille Christophe Michel-Levy* & Alain Lautie†

* Laboratoire de Minéralogie-Cristallographie associé au CNRS, Université Pierre et Marie Curie, 75230 Paris, France † Laboratoire de Spectrochimie IR et Raman, CNRS, 94320 Thiais, France

The Tieschitz H3 chondrite contains 0.25% bulk carbon but concentrations of as much as 2-6% (ref. 2) occur in black, 10-20 µm-wide rims around chondrules that are thought to have accreted before the agglomeration of the stone²⁻⁵. These rims are extremely fine-grained and compact, the main constituent being an iron-rich olivine (Fa 60-65) as shown by a Debye-Sherrer X-ray diffractogram, in good agreement with the FeO/FeO+MgO matrix value2.6. To further our understanding of the rim composition and of the thermal history of the stone, we used the MOLE Raman laser microprobe7 to characterize the carbon constituent. We report here that it is a highly disordered graphite with a progressive ordering as shown by samples heated to temperatures between 300 and 600 °C. Tieschitz could not have been heated to more than 300-350 °C.

Polished sections were prepared from Tieschitz samples previously heated in a nitrogen flux to 300 and 350 °C for 2 h, and to 400 and 600 °C for 1 h. These four samples were then compared with a section of Tieschitz that had not been heated. Areas of interest were precisely located under the microscope and recorded on photomicrographs. The specimens were then transferred to the MOLE microprobe (Jobin-Yvon). The power of the 5,145-A line of a Spectraphysics 160 argon ion laser is 10 mW at the sample surface, thus the laser beam was slightly defocused to avoid degradation of the sample during analysis and the resulting excited area was ~10 µm². The nominal magnification used was ×1,000 and width of the spectral slit was 6 cm⁻¹. As the width of the observed bands was large, the precision of the reported frequencies is ± 5 cm⁻¹. The reported relative intensities were not corrected for the spectrometer yield, thus the 1,605 cm⁻¹ line is underestimated by ~3% compared with the 1,355 cm⁻¹ line.

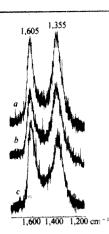

Fig. 1 Raman spectra between 1,100 and 1,800 cm⁻¹ of chondrule rims in the Tieschitz H3 chondrite; a, unheated sample; b, sample heated to 300 °C; c sample heated to 600 °C.

In the 2,500-1,000 cm⁻¹ region, the monocrystalline graphite Raman spectrum exhibits a single band at 1,575 cm⁻¹, whereas polycrystalline graphite and more or less disordered carbon materials show two main bands at 1,605 and 1,355 cm⁻¹, the relative intensities of which depend on the degree of 'graphitization'8-10. The 1,605 cm⁻¹ band, deriving from crystallized graphite, is related to vibrations in the layers. The 1,355 cm band may be assigned to distortion of the hexagonal lattice. The relative intensity ratio of the two bands $\rho = I(1,605)/I(1,355)$ can thus be used as a measure of the imperfection of the graphite layer planes. This was done for carbons heat-treated temperatures between 1,000 and 2,500 °C 9,10 . A relation between ρ and the size of the carbon particles was also found, although it remains to be established whether this is a causal relationship.

About 10 carbon-rich rim areas were studied for each of the Tieschitz sections between 900 and 2,300 cm⁻¹. No detectable degradation of the sample was observed during recording of spectra. To monitor possible effects of degradation, each spectrum was registered in a symmetric mode, sweeping the relevant frequencies both ways. In all cases studied, only the two bands of more or less graphitized carbon were found (Fig. 1). Carbynes, the occurrence of which is questioned in carbonaceous chondrites 11-13 were not detected here.

The relative intensity ratio ρ , determined for each specimen over 10 spectra, shows a deviation of <4% with respect to the mean. This should be ascribed to experimental errors (because of the rather low signal-to-noise ratio) rather than to the existence of real variations. For unheated Tieschitz $\rho = 0.92 \pm 0.03$. This ratio increases with increasing temperature for the heattreated specimens, and thus constitutes a convenient index for the degree of crystallinity of the sample. For t = 300, 350, 400 and 600°C, $\rho = 0.93$, 0.97, 1.05 and 1.23, respectively. In the relatively narrow temperature range investigated, ρ increased linearly with t (Fig. 2). The ρ for unheated Tieschitz is almost indistinguishable from that of the sample heated to 300 °C. We can therefore conclude that Tieschitz, after accretion, was not heated above 300-350 °C. Moreover, the ρ value of 0.92 for the untreated specimen allows us to give an approximate 40 Å limit to the size of the graphite layers occurring in Tieschitz chondrule rims; this corresponds either to crystallite size, or to the size of undisturbed domains. These small particles are dispersed in the entire rim, as the characteristic Raman spectra are identical at any point on the rims.

Independent confirmation of the 300-350 °C heating is given by the nickel-iron alloys that occur in Tieschitz: (1) according to Bevan and Axon¹⁴, interface Ni compositions of contiguous kamacite and taenite grains indicate equilibration to ~350 °C; (2) tetrataenite—the ordered 50% Ni-Fe alloy¹⁵—occurs either as rare isolated grains (their anisotropy is then observable), or in zoned taenite as a clear rim and in association with nickel-poor

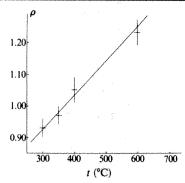

Fig. 2 Intensity ratio of Raman bands at 1,605 and 1,355 cm⁻¹ $\rho = I_{1,605}/I_{1,355}$ obtained on chondrule rims, plotted against temperature.

alloys, giving a cloudy appearance to etched zones. The ordering of this alloy may occur below 320°C and is only observed in slowly-cooled meteorites.

Further microanalyses by Raman spectroscopy of carbon in meteorites will hopefully help us to understand the complex and controversial thermal history of these extraterrestrial rocks.

We thank G. Kurat for the Tieschitz sample and J.-C. Lorin and the reviewers for their advice. This work was supported by CNRS through 'ATP Planétologie INAG' 37.75.

The Yilgarn Block is an ancient crustal block which extends over ~650,000 km² in the south-west of Western Australia and consists of high-grade gneiss and granite-greenstone terrains1. Being one of the largest segments of Archaean crust in the world, it is important to studies of early crustal evolution. We report here a geochronological study of banded gneisses near Mount Narryer, in the north-west of the Yilgarn Block, which has given a Rb-Sr whole-rock isochron age of 3,348 ± 43 Myr with an initial 87Sr/86Sr ratio of 0.7037±0.0005. The data indicate that the rocks had a prior crustal residence time of ~200 Myr. The validity of this early Archaean age is supported by model Sm-Nd ages of 3,510 Myr and 3,630 Myr for two of the samples. Taken together, these ages represent the oldest evolutionary sequence so far identified in the Yilgarn Block, and are comparable with old ages from other Archaean cratons elsewhere in the world.

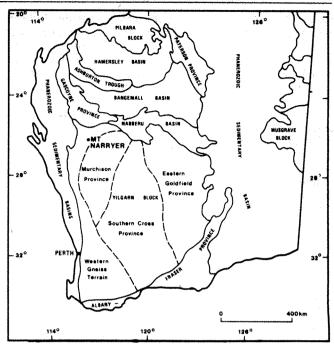

Fig. 1 Distribution of Precambrian tectonic units in relation to Mount Narryer, Western Australia.

Contrasting evolutionary models have been applied to the regional patterns of the Yilgarn Block. One model interprets the gneiss terrains as the metamorphosed and migmatized equivalents of the adjacent greenstones, infolded to deep crustal levels²; the other interprets the gneiss terrains as basement complexes on which greenstones were deposited3.4. However, this debate⁵ is by no means settled, either in the Yilgarn Block, or in other well studied Archaean cratons in the world.

It has been established that the gneisses of the Yilgarn Block occur mainly in an arc >1,000 km long along the western margin of the block, termed the Western Gneiss Terrain (Fig. 1). It was concluded on geological and equivocal geochronological evidence that the gneisses were old basement, and that the greenstone-granite terrains evolved in response to a widespread but relatively short-lived tectonothermal event ~2,700 Myr ago.

The importance of the Yilgarn Block as a reference for early crustal evolution further lies in the nature of the Western Gneiss Terrain. In addition to the extensive areas of banded orthogneiss, there are occurrences of paragneiss in which quartzite, BIF, metacarbonates, metapelite and metaconglomerate occur. The paragneiss is intruded by mafic and ultramafic rocks, now also highly metamorphosed, but with no identifiable volcanics. The paragneiss is clearly 'non-greenstone' in character, and points to sedimentary regimes in the earliest geological record, more uniformitarian than the volcanic regimes of the later greenstones, widely considered to be unique to the Archaean.

The extensive geochronological data for the Yilgarn Block have recently been reviewed⁶. The isotopic dates for most Yilgarn granitoids vary little from the range 2,600-2,700 Myr, and all Rb-Sr ages to date indicate ages for the greenstones in this range, although it has not been unequivocally established that these are volcanic ages as opposed to alteration ages. Early Rb-Sr studies' had indicated that the gneisses near the western margin of the Yilgarn Block may be older than 3,000 Myr. This is confirmed by the present work, and also by zircon U-Pb dates of 3,340 and 3,250 Myr from quartzite and orthogneiss in the Toodyay area, ~90 km east of Perth⁸.

The Rb-Sr data for the samples collected from the Mount Narryer area (26°27' S, 116°24'30" E), in the northern part of the Western Gneiss Terrain, is listed in Table 1 and plotted on an isochron diagram in Fig. 2. A least-squares regression of the data points, using the method of McIntyre et al., yields a slope and intercept corresponding to an age and initial 87Sr/86Sr ratio of 3.348 ± 12 Myr and 0.70383 ± 0.00008 (2 σ errors), with a

 0.85482 ± 14

MSWD = 10.8. The relatively large value for the MSWD indicates that the data do not fit within experimental error, and that some isotopic remobilization may have occurred. Therefore a more realistic evaluation of the age and initial ratio of the banded gneiss is that provided by model 4 (ref. 9), which gives 3.348 ± 43 Myr and 0.7037 ± 0.0005 (2 σ errors).

The samples were collected from a site ~13 km due west of Manfred Homestead and 9 km north-northeast of Mount Narryer 'trig' point. The Mount Narryer rocks are a high-grade amphibolite-granulite transition facies metasedimentary sequence. All samples are banded quartz-feldspar-biotite gneiss of granodiorite to adamellite composition. Microcline is present in all samples and plagioclase exists as oligoclase. Samples rich in quartz and microcline contain metamict allanite. All samples have been redeformed and recrystallized beyond the primary gneissose structure and in part are protomylonitic. Plagioclase is lightly saussuritized and biotite has been recrystallized and in part chloritized in the course of redeformation of the gneiss. Sample 60739 is largely epidote and has been excluded from the isochron.

Strontium evolution analysis of the data from Mount Narryer suggests a mantle evolution age of 3,550 Myr assuming singlestage evolution. This value was calculated from the determined age (3,348 Myr), the initial 87Sr/86Sr ratio (0.7037) and the arithmetic mean of measured ⁸⁷Rb/⁸⁶Sr ratios (1.32). Mantle Sr evolution was assumed to be linear from 0.6990 at 4,600 Myr to 0.7037 at present¹⁰. The projected path of strontium isotope evolution in the sample intersects the modelled mantle development curve at 3,550 Myr at a 87 Sr/ 86 Sr ratio of 0.7000. An independent determination of 0.700 for the initial 87Sr/86Sr ratio of a 3,350 Myr gneiss from the South Indian Craton¹¹ suggests that the mantle model which was used is realistic. On these assumptions, prior crustal residence of $\sim 200 \,\mathrm{Myr}$ is

As a test of the hypothesis that the gneisses at Mount Narryer had a substantial crustal residence time before the effects of dynamic metamorphism reset the Rb-Sr isochron at 3,348 Myr, Sm-Nd model ages were determined for two of the samples in the suite, as this geochronological technique has some advantages over the Rb-Sr method in determining ages of differentiation of crustal rocks from the mantle. The analytical data are given in Table 2.

The model $T_{\text{Chur}}^{\text{Nd}}$ ages of 3,510 Myr and 3,630 Myr are consistent with a crustal residence time of ~200 Myr for the gneisses that yield the Rb-Sr whole-rock isochron age of 3,348 Myr. The earlier ages are interpreted as the time of extraction of quartzo-feldspathic material, probably as granitic melts from the mantle; and the later age is taken to represent the age of the gneiss that was derived by metamorphic reworking of the primeval quartzo-feldspathic material.

Table 2 Samarium-neodymium analytical data, Mount Narryer

Sample	¹⁴⁷ Sm/ ¹⁴⁴ Nd	¹⁴³ Nd/ ¹⁴⁴ Nd	fsm/Nd End	T CHUR (Myr)
60734	0.07892 ± 23	0.509884 ± 30	-0.5988 -53.4	3510 ± 50
60735	0.08751 ± 26	0.509996 ± 20	-0.5551 -51.2	3630 ± 40
BCR-1		0.51263 ± 3	and the second second	maintable

The samples were digested in HF/HClO₄/HCl acids in a Teflon bomb. A portion of each sample was spiked with a ¹⁴⁷Sm/¹⁵⁰Nd dual tracer, and the spiked and unspiked samples were separated using ion exchange procedures. Both Sm and Nd were analysed on triple rhenium filament assemblies as Nd^+ and Sm^+ ions. Nd isotopic ratios were measured with respect to ^{142}Nd and corrected for fractionation using $^{146}Nd/^{142}Nd=0.632265$ (ref. 12). Evidence for Ce contamination was checked at mass 140. The uncertainties are 95% confidence limits. The analytical blank contributed <1 part in 10^4 of the total Nd. $f_{\rm Sm/Nd}$, $\varepsilon_{\rm Nd}^{\rm Nd}$ and $T_{\rm CHUR}^{\rm Nd}$ are calculated using ($^{147}{\rm Sm}/^{124}{\rm Nd})_{\rm CHUR}^0$ = 0.1967 and ($^{143}{\rm Nd}/^{144}{\rm Nd})_{\rm CHUR}^0$ = 0.51262 (ref. 13).

These data strongly support the emerging picture in the Yilgarn Block of an ancient gneiss basement, now exposed in the west, overlain by greenstones, now exposed in the central part. Additional comparative Sm-Nd and Rb-Sr studies are planned on regional transects up to 800 km in length, across the greenstone terrains to clarify the chronological relations between the gneiss and greenstones, and to detect any regional variation in greenstone ages. Such studies may help distinguish between a model of lateral accretion of successively younger greenstones away from an embryonic craton, or a single widespread event of greenstone accumulation on a continuous basement. This may also clarify the curious situation observed in the Yilgarn Block of younger rocks occurring on the concave side of an arcuate belt of older rocks, a feature that does not fit with an island-arc accretionary model.

We thank Dr A. F. Trendall of the Geological Survey of Western Australia for permission to publish this work, and D. J. Hosie for technical assistance. The project was supported by the Australian Research Grants Committee.

Nd and Sr isotopic relationships in pelagic clays and ferromanganese deposits

S. L. Goldstein

Lamont-Doherty Geological Observatory and Department of Geological Sciences, Columbia University, Palisades, New York 10964, USA

R. K. O'Nions

Department of Earth Sciences, University of Cambridge, Downing Street, Cambridge CB2 3EQ, UK

The concentrations of heavy metals in seawater are exceedingly low and commonly less than 10^{-9} g per g. In marked contrast, their concentrations in pelagic clays and ferromanganese deposits occurring on the ocean floor are many orders of magnitude greater. This relationship is a reflection of both the low solubilities of heavy metals in seawater and their efficient sequestering from seawater by particulates. The behaviour of the heavy metal neodymium in the marine environment is further investigated in this study through the useful natural isotope tracer ¹⁴³Nd. ¹⁴³Nd/¹⁴⁴Nd and ⁸⁷Sr/⁸⁶Sr ratios are reported for hydrogenous ferromanganese sediments, the lithic substrate of a manganese nodule and pelagic clay samples occurring close to manganese nodules. Common sources for Nd in clays, ferromanganese deposits and pelagic clays are demonstrated, but significant differences exist between the Atlantic, Indian and Pacific Oceans.

Ferromanganese sediments are broadly divisible into hydrogenous and hydrothermal deposits¹. Hydrogenous deposits are considered to form by slow (0.1-1.0 mm Myr⁻¹) precipitation of Fe and Mn (refs 2-4) and include ferromanganese pavements on marine topographic highs, and concretions on abyssal plains. Hydrothermal deposits are considered to form by much more rapid (1-10 mm kyr⁻¹) precipitation of Fe and Mn (refs 3, 5) and include basement associated ferromanganese crusts and the so-called metalliferous sediments⁶⁻⁹.

The sources of elements incorporated into ferromanganese deposits vary according to the type of deposit and geographical location. Although the continents are usually considered to be the major source of the Fe and Mn in hydrogenous deposits, submarine volcanism may also contribute in some areas 10. Even within a single deposit, the provenances of the different major, minor, and trace elements may not be the same. Whilst Fe and Mn in metalliferous sediments occurring at the East Pacific Rise are thought to be derived predominantly from oceanic basalt^{8,9,11}, the isotopic compositions of O, S, Sr and U in these deposits differ from those found in oceanic basalts and are compatible with a seawater origin^{8,9}. Further, although Pbisotope compositions in the East Pacific Rise deposits are within the range found in mid-ocean ridge basalts^{9,12}, the range of Pb-isotope compositions in Pacific hydrogenous ferromanganese deposits encompasses many of the variations found in oceanic basalts and pelagic clays¹²⁻¹⁴.

In contrast with the large variability of Pb isotope compositions, the 143Nd/144Nd ratios of all measured Pacific hydrothermal and hydrogenous ferromanganese deposits vary within a narrow range, and are less than those measured for Recent mid-ocean ridge basalts and also less than the value for the model bulk Earth (Fig. 3a). These observations suggest that the

Nd in these deposits is predominantly continent-derived.

The median ¹⁴³Nd/¹⁴⁴Nd ratio of Pacific Ocean surface ferromanganese deposits is greater than for the Indian Ocean. which is in turn greater than the median ratio for the Atlantic Ocean (Fig. 3a). In each case, the ¹⁴³Nd/¹⁴⁴Nd ratios vary within a small range (less than $\pm 2 \times 10^{-4}$), indicating that each ocean is isotopically well-mixed with respect to Nd. ¹⁴³Nd/¹⁴⁴Nd ratios in seawater samples from the Pacific and Atlantic oceans are within the range of 143Nd/144Nd ratios for ferromanganese deposits within these oceans 15.16. 87 Sr/86 Sr ratios of all surface ferromanganese samples measured cluster around the present day seawater value (0.7091). These observations raise questions concerning the mechanisms by which different elements are transported to their sites of deposition. An understanding of such mechanisms must involve identification of the ultimate provenance of the elements, their fluxes between different reservoirs, and the degree of mixing within each reservoir. This study investigates the behaviour of Nd and Sr in the marine environment and focuses on the isotopic relationships of Nd in ferromanganese deposits and spatially related pelagic clays.

The locations of ferromanganese and oceanic clay samples analysed, together with locations of ferromanganese, pelagic clay and seawater samples previously analysed for Nd isotopes 12.15-17, are shown in Fig. 1. All of the Nd and Sr isotope analyses reported in Table 1 were made at the Lamont-Doherty Geological Observatory using techniques previously described 18,19. For those samples leached with acetic acid (HOAc), isotope data are reported for both leachates and

residues (Table 1).

The ¹⁴³Nd/¹⁴⁴Nd ratios for samples of surface ferromanganese deposits from the Pacific and Indian oceans (Fig. 3, Table 1) fall within the ranges reported previously for samples from these oceans 12,16. Sample D-9, described elsewhere5, from the Galapagos spreading axis consists of a hydrothermal ferromanganese crust layer in contact with a hydrogenous ferromanganese crust. The hydrothermal crust was deposited at, or near, the ridge axis, whereas the hydrogenous crust was apparently deposited at a locale where hydrothermal effects were absent. The ¹⁴³Nd/¹⁴⁴Nd ratios obtained for these distinct layers (Table 1) are indistinguishable and fall within the narrow range found for all other ferromanganese and seawater samples from the Pacific Ocean (Fig. 3a), which range from 0.5124 to 0.5126. 143 Nd/144 Nd ratios in ferromanganese samples from the Atlantic and Indian oceans are significantly lower than the Pacific Ocean samples and range from about 0.5119 to 0.5122 (Fig. 3a). The median of the Atlantic Ocean samples is at a lower 143 Nd/ 144 Nd ratio than the median of Indian Ocean samples, but the larger range of values for the Atlantic Ocean samples does indicate real variability of provenance. Piepgras and Wasserburg¹⁶ have shown that measurable variability in ¹⁴³Nd/¹⁴⁴Nd ratios extends to different depths within the same water column in the Atlantic Ocean. The total range of measured Atlantic seawater values is within the range found for Atlantic ferromanganese deposits. The relative differences in the 143Nd/144Nd ratios found in the Atlantic compared with the Pacific samples are compatible with an older overall crustal source of Nd in Atlantic ferromanganese deposits compared with Pacific

As part of a general survey of pelagic clays, 143Nd/144Nd ratios are presented in Table 1 for surface clay samples from the Atlantic, Indian and Pacific oceans (Fig. 1) that are spatially related to manganese nodules. The 143Nd/144Nd ratios of Indian and Atlantic samples are within the ranges established for the ferromanganese deposits from the same ocean (Fig. 3a, b), which suggests that the provenance of Nd in both clays and ferromanganese deposits within these oceans are closely related. The reported ¹⁴³Nd/¹⁴⁴Nd ratio of 0.512423 ± 21 for an eastern Pacific Ocean clay sample 17, is within the range established for Pacific Ocean ferromanganese deposits. Three clay samples

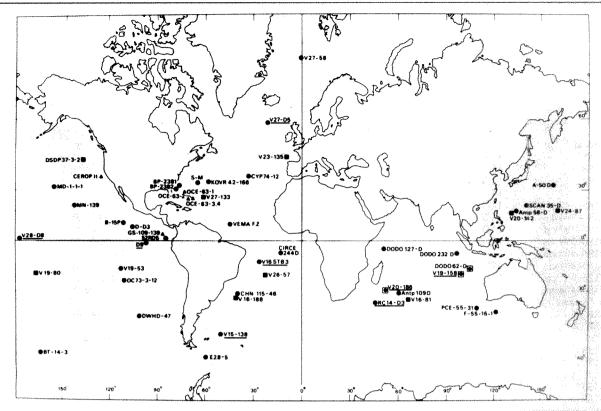

Fig. 1 Location of ferromanganese deposits (●) analysed as part of this study (underlined) and previously published ^{12,15}. Seawater sites (▲) from refs 15, 16. Locations of pelagic clay samples analysed as part of this study (□, ■) and red clays (DSDP-37-3-2 and DODO-62D) from refs 17, 15 respectively.

from the western Pacific (Table 1, Fig. 3b) have 143Nd/144Nd ratios close to 0.5122, lower than those of manganese nodules sampled from similar locations, indicating a decoupling between Nd in clays and nodules. In contrast, data for the Atlantic and Indian oceans suggest that Nd in both clays and nodules may be of the same derivation. If, for example, Nd in western Pacific manganese nodules is simply considered to be a mixture of a component isotopically similar to western Pacific pelagic clays 3Nd/14 4 Nd ≈ 0.5122) and a basaltic component $(^{143}\text{Nd}/^{144}\text{Nd} \simeq 0.5130)$, then the latter component would comprise ~25% of the Nd in these nodules. It remains to be shown whether the higher mean seafloor spreading rate in the Pacific compared with the Atlantic and Indian oceans is the cause of these observations.

The relationship between Nd and Sr isotopes in a manganese nodule (located at a depth of 400 cm in Vema core V20-186 from the Indian Ocean) and the enclosing lutite has been examined in addition to the general survey of pelagic clays. Six samples of sediment from above and below the manganese nodule, together with two samples of the nodule itself, were leached with HOAc. Measured ⁸⁷Sr/⁸⁶Sr ratios for leachates and residues, and ¹⁴³Nd/¹⁴⁴Nd ratios for the residues (Table 1, Fig. 2) demonstrate the existence of an HOAc leachable component in both the clays and the nodule with a 87Sr/86Sr ratio close to 0.709, the present day value of seawater. The 87Sr/86Sr ratios of clay residues are greater than 0.726. Those for the nodule residues are close to 0.710, significantly higher than present day seawater, and may reflect occlusion of some clay in the nodules. Although typical concentrations of Nd in manganese nodules are nearly an order of magnitude higher than pelagic clays²⁰, the ¹⁴³Nd/¹⁴⁴Nd ratios of the lutite and manganese nodule samples are very similar with a total range of 0.511940-0.512011 (Table 1, Fig. 2), and this cannot be attributed to the inclusion of clay into the nodules. This contrasts with the greater differences in Sr/86Sr ratios between the manganese nodule and lutite and suggests that, in contrast to Sr, the provenance of Nd in the lutite and the nodules may be the same. 143Nd/144Nd ratios for clay and nodule samples from the top of a second Indian Ocean core

(V19-158) are 0.512128 ± 24 and 0.512214 ± 28 respectively. These results are similar to the ratios obtained for an Indian Ocean clay-nodule pair $(0.512140\pm25$ and 0.512246 ± 26 respectively)¹⁵. In both cases the ¹⁴³Nd/¹³⁴Nd ratios of the clay and nodule samples are within the range of all Indian Ocean surface samples measured (Fig. 3a, b).

The relationships between the ¹⁴³Nd/¹⁴⁴Nd ratios in surface

ferromanganese deposits and pelagic clays within each ocean suggest that the Nd budget of ferromanganese deposits may be dominated by the same source that supplies pelagic clays. Ferromanganese deposits have a minor role in the overall Nd budget of the oceans. The largest repository of Nd in the ocean basins is pelagic clay (~40 p.p.m. by weight of Nd). Although manganese nodules possess a higher concentration of Nd than pelagic clay²⁰, the ratio of the rate of Nd accumulation in manganese nodules relative to pelagic clay is estimated (Table 2) to be about 0.05. The more restricted occurrence of manganese nodules limits the ratio of total accumulation in nodules to clay

MN, manganese nodule; HGC, hydrogenous crust; HTC, hydrothermal crust; LUT, lutite; SUBST, lithic substrate of nodule V16-SBT3. 143 Nd/ 144 Nd data normalized to 146 Nd/ 144 Nd = 0.7219. 87 Sr/ 86 Sr ratios expressed relative to 87 Sr/ 86 Sr = 0.70800 for Eimer and Amend SrCO₃. Measured value for this standard is 0.70806.

Reported errors are 2σ on the mean.

to $\ll 0.05$. The total mass of Nd dissolved in seawater, $\sim 4 \times$ 109 kg using Hogdahl's²¹ estimate for the concentration of Nd in seawater (Table 2), is trivial compared with the mass of Nd in pelagic clay. For example, a mere 0.4 mm of abyssal carbonatefree sediment is estimated to contain an amount of Nd equal to the total dissolved Nd in a water column of average depth (Table 2). A much larger sediment depth maintains contact with seawater by bioturbation processes. In other words, a particulate clay concentration in seawater of 75 µg l⁻¹ would possess an amount of Nd equal to the estimated average dissolved load. Note that the pelagic clay sedimentation rate estimates suggest that seawater should contain an average of $\sim 50 \mu g l^{-1}$ of particulate material, or an amount of Nd in particulate material approximately equal to the dissolved load (Table 2). Particulate concentrations are much higher than average in the nepheloid zone, which contains pelagic clay swept back up into the water column, and may extend 1,000 m above the sediment-seawater interface.

An outstanding problem is the mechanism by which the related ¹⁴³Nd/¹⁴⁴Nd ratios in ferromanganese deposits, pelagic clays and seawater are established. For example, continual cation exchange between pelagic clay and seawater, particularly within the nepheloid zone, may control the Nd isotope composition of seawater. If cation exchange is the controlling factor, then the ¹⁴³Nd/¹⁴⁴Nd ratios of western Pacific pelagic clays require that some of the Nd in the clay be isolated from chemical contact with seawater, as occurs with Sr (ref. 22). Addy²³ has interpreted rare-earth element (REE) abundance patterns in Atlantic red clays in terms of a detrital Nd component (\approx 90%), and a hydrogenous component (\approx 10%). The hydrogenous component must be sequestered from seawater, and may preferentially exchange with it.

Degradation of particulate material in river systems provides the initial source of marine Nd; however, the 143 Nd/144 Nd ratios of water and particulates in different rivers are likely to be highly

variable. Even though some 98% of the annual river flux of Nd is in particulate material^{24,25}, the estimated average concentration of dissolved Nd in river water is over an order of magnitude higher than in seawater²⁴⁻²⁶. If the dissolved Nd concentration in seawater is at a steady state, the excess Nd in river water must be sequestered by particulate material in the oceans, and may constitute a portion of the Nd in the hydrogenous REE component of pelagic clays. The small but distinct range of ¹⁴³Nd/¹⁴⁴Nd ratios in ferromanganese deposits and seawater within each ocean is therefore a function of the residence time of Nd in seawater, the kinetics of any important exchange processes, and intra- and inter-ocean mixing times.

Estimates of the oceanic Nd-residence time 27,28 ($\approx 2-3 \times$ 10² yr) are comparable to estimates of the residence time of Pb

Table 2 Mass balances and residence time of Nd in ocean basins

Average concentration of Nd in seawater ²¹	$2.8 \times 10^{-9} \mathrm{g l^{-1}}$
Thickness of pelagic sediment (averaged, over oceans) containing mass of Nd equivalent to that in seawater	0.4 mm
Mass of clay particulate containing equivalent	$\sim 7.5 \times 10^{-5} \text{ g}$
amount of Nd as 1 litre seawater	7,57,10 8
Average amount of non-carbonate detrital particulate in seawater	$5 \times 10^{-5} \mathrm{g}\mathrm{l}^{-1}$
$\tau_{\rm Nd}$ (residence time of Nd) assuming particulate Nd isolated from dissolved Nd	3,100 yr

Calculations assume steady state and the following: Nd concentration in pelagic clay equal to average North American shale = 37 p.p.m.; density of dry abyssal sediment = 0.7 g cm^{-3} (ref. 3); abyssal non-carbonate sedimentation rate = $10^{-4} \text{ g cm}^{-2} \text{ yr}^{-1}$ (ref. 3); mean ocean depth = 3,729 m (ref. 3); pelagic sediment $\sim 90\%$ carbonate (ref. 3); manganese accumulation rate in nodules = 10^{-6} g cm⁻² yr⁻¹ (ref. 3); Nd concentration in river water = 3.79×10^{-7} g l⁻¹ (ref. 25); H₂O flux from rivers in oceans = 3.2×10^{16} 1 yr⁻¹ (ref. 38).

Unlabelled boxes are manganese nodules. b, Histogram of pelagic clay samples from this study together with a sample from ref. 17 and one from ref. 15. All 143 Nd/ 144 Nd ratios are relative to 146 Nd/ 144 Nd = 0.7219.

(refs 29-33). In these estimates the abundance term is based on the concentration of dissolved Nd in seawater, and the input term is based on the total load of Nd entering the oceans per year. The actual residence times will be greater than these minimum values if portions of the REE which enter the oceans are isolated from chemical contact with seawater, as is indicated by the western Pacific clays. If the REE within particulates are completely isolated from seawater, for example, τ_{Nd} may be as long as 3,100 yr. The intra-ocean uniformity and inter-ocean differences in the 143Nd/144Nd ratios of surface ferromanganese deposits contrasts with the intra-ocean variability of Pb isotope ratios, and implies that τ_{Nd} is greater than τ_{Pb}

There have been various opinions on the direct source of the REE incorporated into ferromanganese deposits. Goldberg et al.27 noting the similarities between rare-earth patterns of manganese nodules and seawater, favour direct precipitation of the REE from seawater. Their suggestion has been supported for both manganese nodules 12,20,34,35 and East Pacific Rise metalliferous sediments^{8,9,12}. Ehrlich³⁶ and Bender³⁷, on the other hand, suggest that REE are incorporated into manganese nodules from proximal clay either by surface transfer mechanisms, or by clay occlusion into the nodule. The apparent conformability of Nd isotope ratios in Pacific seawater samples and ferromanganese deposits has led Piepgras et al. 15 to favour seawater as the source of Nd in ferromanganese deposits. A distinction between a seawater or pelagic clay source of Nd in manganese nodules cannot be determined from the results on Atlantic and Indian ocean samples (Fig. 3a, b). However, the demonstrated decoupling between Nd in clay and manganese nodules in the western Pacific suggests that Nd in the manganese nodules is not representative of the total Nd in the clay. Although pelagic clay may contain both labile and non-labile Nd components, the simplest explanation of the data on hand is to invoke seawater as the direct source of the REE in manganese nodules.

143Nd/144Nd ratios in surface pelagic clay samples from different oceans exhibit the same general relationship as those from ferromanganese deposits. That is, the median 143Nd/144Nd ratio of Pacific Ocean clays is higher than the median of Indian Ocean clays, which is in turn higher than the median of Atlantic Ocean clays. This result demonstrates the domination of continent derived detrital material in controlling the Nd-budget of clavs, ferromanganese deposits and seawater within each ocean basin, and highlights the differences between them.

W. S. Moore provided sample D-9. This research was supported by the NSF EAR-75-20891, the Royal Society, and a fellowship for S. L. Goldstein from the Department of Geological Sciences, Columbia University. Department of Earth Sciences contribution no. E.S. 158, L. D.G.O. contribution no. 3169.

Antarctica offers a unique natural environment from the point of view of nitrogen cycling. Ice-free dry areas, 'Antarctic oases', and penguin rookeries are of particular interest because of the characteristic distribution of nitrate deposits 1-4 and biological materials such as algae and guano. As the distribution of 15 N/14N in a geochemical system reflects sources and metabolic pathways of nitrogen⁵, a study of the nitrogen isotopic composition of Antarctic samples would help us to understand the Antarctic nitrogen cycle. Here we report that nitrate in Antarctic soils is extremely depleted in 15N compared with biogenic nitrogen, and that algae collected from a nitrate-rich saline pond and from a penguin rookery exhibit, respectively, the lowest and the highest ¹⁵N/¹⁴N ratios among terrestrial biogenic nitrogen so far observed. We also discuss possible causes of these extreme nitrogen isotopic compositions.

'The Dry Valleys' in southern Victoria Land, McMurdo Sound region is a large polar desert extending over an area of $\sim 2,500 \text{ km}^2$ and containing several valley systems—Wright Valley being the most famous. Precipitation is $< 100 \text{ mm yr}^{-1}$ and mean air temperature is between -18 and -25 °C. Fallen snow is mostly dissipated by sublimation, but melting of glaciers occurs during the warm season and produces fresh and saline lakes and ponds where algal communities flourish. According to Webb⁶, the Wright Valley was below sea level in the Pliocene (3-4 Myr BP).

Soil materials and algal samples were collected from Wright Valley and Cape Bird in Ross Island in January 1979. Procedures for isotopic analysis were described elsewhere^{7.8}. Nitrogen isotopic composition is expressed as follows:

Nitrogen isotopic composition is expressed as follows:
$$\delta^{15}N(\%) = \left\{ \frac{\binom{1^5N/^{14}N)_{\text{sample}}}{\binom{1^5N/^{14}N}_{\text{air}}} - 1 \right\} \times 1,000$$

Water soluble salts were analysed by the following methods: for ammonium, phenol-hypochlorite method⁹; for nitrate, diazotization method¹⁰; for nitrate, cadmium reduction method¹¹; and for chloride, mercuric thiocyanate method¹². Organic nitrogen was determined by Kjeldahl digestion¹³.

Nitrate was the major component among nitrogenous compounds in Antarctic soils (Table 1). Concentrations of organic nitrogen (0.34-6.4 μ g atom N per g dry soil) were one to two orders of magnitude lower than those of nitrate except for samples collected from a penguin rookery, Ross Island. Our data of δ^{15} N for soil nitrate in Antarctica exhibited quite low values (-11 to -24%). The minimum value of -23.4% was found for soil materials collected from a slope of a U-shaped valley near Lake Vanda. The natural abundance of ¹⁵N in biogenic nitrogen in the literature generally ranges from -17 to +20%. The average δ^{15} N values for nitrate are: 3.2% for forest soils; 6.4% for cultivated soils; 7.0% for oceanic waters; and

-6.6% for rain waters¹³⁻¹⁵. The δ^{15} N values for Antarctic nitrate were, thus, quite different from that for oceanic nitrate, and gave the lowest ranges among terrestrial nitrate.

Various origins have been considered for the salts in the Dry Valleys: direct marine incursion16, marine aerosols or sea spray³, chemical weathering of minerals¹⁷, and NO_x produced by auroral activities¹⁸. According to Moore¹⁹, gaseous ammonia (-10.0%) and nitrogen dioxide (-9.3%) in clean air are depleted in 15N as compared with those in aerosols (NH₄, +5.6% and NO₃, 5.0%). He interpreted the low ¹⁵N content in gaseous compounds as being due to the nitrogen isotope fractionation associated with isotopic equilibria between gaseous and condensed phases with subsequent removal of the condensed phase. The successive removal of the condensed phase during long distance transportation from the tropical and temperate region to the polar region may further enhance depletion of 15N in nitrogenous compounds in the atmosphere of the polar region. The $\delta^{15}N$ data suggest that nitrate in Antarctica soils is mainly derived from atmospheric precipitation which carries NO_x depleted in ¹⁵N. NO_x depleted in ¹⁵N might be produced by photochemical reactions³ as well as by auroral activities¹⁸. No other processes can produce nitrogen oxides of such low δ^{15} N.

In the case of algae, $\delta^{15}N$ values ranged between -49 and +30% (Table 2). The lowest value (-49%) was found for the algae collected from a small saline pond located near the edge of Wright Upper Glacier. This is the lowest $\delta^{15}N$ value ever reported for terrestrial samples. It has been demonstrated that the isotope fractionation during nitrate assimilation by a marine diatom, *Phaeodactylum tricornutum*, is inversely related to its growth rate at low light intensities and a high nitrate concentration (10 mg atom NO_3^-N l⁻¹). A fractionation factor as high as 1.03 has been obtained as an extreme. A characteristic feature of Antarctic saline ponds is the high concentration of nitrate

in this pond was 8.7 mg atom NO₃-N l⁻¹. Growth of the epibenthic algae at high nitrate concentration and low light intensity may thus be accompanied by a large nitrogen isotope fractionation. The extremely low $\delta^{15}N$ values for the epibenthic algae can thus be explained by the combination of low $\delta^{15}N$ for source nitrate and large isotope fractionation associated with nitrate assimilation.

High ¹⁵N enrichments of +30.7 and +28.6% were found in algal felt and organic nitrogen collected from the Adelie penguin rookery at Ross Island, respectively (Table 2). The enrichment of ¹⁵N along a food chain has been reported elsewhere²². The 815N value for marine plankton ranges from 2 to 5% and for fishes from 15 to 20% (ref. 22). Adelie penguins at Cape Bird feed on krill and fish, and deposit faecal materials including uric acid in the soils of the rookery. Soil microorganisms convert uric

acid and other organic nitrogen to ammonia which evaporates with a high nitrogen isotope fractionarion. This may leave nitrogenous materials rich in ¹⁵N in soils. Kreitler⁷ obtained an apparent fractionation factor of 1.038 for NH₃ volatilization from barnyard soils. In the cold climate of Antarctica, the biogeochemical processes in question might proceed at an extremely slow rate. If so, a much greater fractionation of the nitrogen isotope is expected, and the high 15N enrichments in organic nitrogen and algae in the penguin rookery can be explained.

Torii et al.²¹ observed a high pH of 9.4 in the surface water of Lake Canopus where intensive photosynthesis occurred. The isotope fractionation associated with ammonia volatilization thus also explains 15N enrichment of epibenthic algae in this lake (C-2 in Table 2).

Chemical flux in an acid-stressed stream

Ronald J. Hall* & Gene E. Likens

Section of Ecology and Systematics, Division of Biological Sciences, Cornell University, Ithaca, New York 14850, USA

The acidity of rain and snow falling on widely separated areas of the world has been increasing during the past 30 yr (refs 1-3). Acid rainfall consists of a dilute solution of sulphuric and nitric acids due to the oxidation and hydrolysis of airborne sulphur and nitrogen⁴ and frequently has a pH of <4.0. Recent studies have shown that acid rain alters the chemistry and biology of streams and lakes in large regions of the world. Results from reconnaissance studies in the field. and physiological studies in the laboratory show that diversity and numbers of aquatic organisms of all major trophic levels are affected by low pH (high acidity). The quantitative effects of such acidification on biogeochemistry and biological function in natural streams have received little attention. In contrast, much is known about aquatic ecosystems affected by acid mine drainage^{10–13} However, waters receiving acid mine drainage show effects caused by metal contamination and deposition of iron oxide particulates, as well as acidification. In our study, we experimentally acidified a third-order section of a small mountain stream in the Hubbard Brook Experimental Forest, West Thornton, New Hampshire, USA. Our aim was to measure the effects of increased acidity on chemical and biological export in the stream. It was found that experimental stream acidification to pH 4 did alter the chemical and biological flux. The most significant inorganic component affected by the experiment was alaminium. A significant net flux of carbon and nitrogen occurred in the biologically bound forms but not in dissolved substances. Net flux of phosphorus was significant in biologically bound forms. The increased loss of nutrients in the particulate organic fraction was also important, particularly if scaled to the total stream ecosystem. ..

Areas affected by acid precipitation are often located in northern latitudes where snow accumulates during long, cold winters. Snowmelt in spring then releases a large quantity of water and ions to streams and lakes 14,15. For example, on average, 54% of the annual streamwater discharge within the Hubbard Brook Experimental Forest occurs between March and May, with as much as 30% occurring in April¹⁵. It has been reported that when snow thaws, the first portions of the melt water may be very acidio¹⁶. Thus in such areas, late winter or early spring thaws may cause sudden decreases in pH in aquatic ecosystems. During such snowmelt periods, pH values as low as 4.0 have been recorded in streams in Norway¹⁷, in the Adirondack Mountains of New York State 18, and in the Hubbard Brook Experimental Forest, New Hampshire (N. Johnson, personal communication). Trout deaths have been observed in Norwegian streams during flushes of acidic melt water¹⁷.

Our study was done at Norris Brook, a tributary of Hubbard Brook 19-21. This stream flows through deciduous forest underlain by granitic bedrock and is subject to inputs of sulphuric and nitric acids in rain and snow at an annual volume-weighted pH near 4 (range 2.85 (ref. 22)-5.95 (ref. 15) for individual storms). The annual pH of Norris Brook in the study area normally ranges from 5.4 to 6.4. We experimentally decreased the pH of a third-order section of the stream to 4 (range 3.9-4.2) by continuously adding sulphuric acid (0.05-0.5M) from 18 April to 22 September 1977. The experimental design and biological effects for the entire study are detailed elsewhere 19-21. Sampling stations for the reference area (A) and the treatment area (B) were located 1 m above and 15 m below the acid addition point, respectively. The treatment reach of the stream between points A and B was $26.9 \text{ m}^2 \pm 0.6 \text{ (f} \pm \text{s.e.}, n = 3)$ in area. The effects of hydrogen ion stress on the biogeochemistry of the stream are described here for the first 30 days (18 April to 17 May 1977). We separated our results into the first 5 days ('acute response') and the remaining 25 days ('chronic response') of hydrogen ion stress. A mass-balance approach was used in which the inputs to the treatment area minus the outputs yielded a net flux of chemicals from the area during the experimental period.

Methods for collection of water samples and chemical analysis are detailed elsewhere 20. For fine particulate organic matter (FPOM) measurements, aliquots of stream water were filtered through ashed 0.45-µm glass fibre filters. Filters were dried for ~2 days at 60 °C. Carbon concentrations of the particulate

^{*} Present address: Ecosystems Research Center, Center for Environmental Research, Cornell University, Disco., New York 14853, USA.

Table 1 Mean daily biomass flux of drifting invertebrates and coarse particulate organic matter (CPOM), and flux of fine particulate organic matter (FPOM) and selected dissolved substances (Ca, Al, N, organic carbon) during 5-day (acute response) and 25-day (chronic response) periods of increased hydrogen ion stress

Site A was in the reference area and just upstream of the treatment area; site B was at the downstream end of the treatment section. The durations of the acute and chronic responses were determined by a dose-response curve of drift density (biomass per volume of water). For the first 5 days of depressed pH, the density of invertebrate drift leaving the acidified zone exceeded that entering by a factor of 1.7-3.3, with peak drift appearing only after 2 days of acid addition. For the remaining 25 days, drift density at the treatment site was 1.6-fold greater than at the reference site. The mean daily (\pm s.e., n = 5) streamwater concentrations at site A for Ca, Al, N and DOC during the 5-day period were 1.65 ± 0.012 , 0.01 ± 0 , $0.01 \pm$

matter were determined by conversion to CO₂ and IR gas analysis²³. A conversion factor of 2.22 (ref. 24) was used to change fine particulate organic carbon to FPOM.

Drift nets were positioned upstream and downstream of the acid addition point²⁰. Invertebrates and coarse particulate organic matter (CPOM) collected in drift nets were dried to a constant weight at 60 °C. CPOM is defined as all materials (conifer and deciduous leaves, very small branches, and other organic particulates) retained in the 253-um mesh drift nets. Chemical analyses of the invertebrates and organic matter were done using a conductive Jarrell-Ash (model 975) Multi-Channel Plasma Atom-COMP/Flame Emission spectrophotometer and a Perkin-Elmer (model 303) spectrophotometer, respectively. The coefficient of variation for chemical concentrations in invertebrates and organic matter ranged from 5 to 28% for all samples. We determined the net flux (A-B) of invertebrate, particulate (CPOM, FPOM), and dissolved (Al, Ca, N and organic carbon) transport modes operating in our experimental area (site B) relative to the reference section (site A). Biomass flux of invertebrates and particulate (CPOM and FPOM) matter is the product of chemical concentration (mg per g) and mass of biota collected per unit time (g day⁻¹), whereas streamwater flux (dissolved ions) is the product of chemical concentration (mg l^{-1}) and discharge of water (1 day⁻¹).

A comparison of some of the major biotic and abiotic components between the upstream and downstream sites yields information on acute and chronic effects of hydrogen ion stress (Table 1). The biomass of exported invertebrates and concentration of dissolved Al were higher in the acidified area (site B), with the per cent net loss $[100(input-export)(input)^{-1} = net$ ecosystem flux] being greater during the first 5 days than during the remaining 25-day period (negative values equal loss and positive values equal gain between A and B, Table 1). For example, a 285% (Students' t, one-tailed, P < 0.025) and 58% (P < 0.025) net loss of invertebrate biomass from the acidified zone (26.9 m² study area) occurred during the 5-day (acute) and 25-day (chronic) periods, respectively; a 160% (P < 0.005) and 86% (P < 0.05) net loss of dissolved Al occurred during these same two periods. Although the net export of CPOM increased significantly (107%, P < 0.01) after just 5 days of acidification, the net flux of FPOM (P > 0.25) and dissolved Ca, N and organic carbon did not change (Table 1). Thus, increased acidity augmented the export of biomass and some dissolved chemicals to downstream reaches with a higher rate of loss occurring immediately after acidification.

Concentrations of Al, Ca, C, N, P and S in invertebrate biomass and CPOM were determined (Table 2), and the net flux (concentration \times mass per unit time) of each element between site A and B is shown in Fig. 1a (acute period) and b (chronic

period). The net flux (A-B) of these elements in the dissolved fraction (from Table 1) is also included in Fig. 1. A significant increase in net flux of Al, Ca, C, N, P and S in invertebrate biomass (P < 0.01) occurred for the 30-day period (Fig. 1a, b). A significant net flux of these six elements in the CPOM fraction occurred during the 5-day study period (P < 0.01, Fig. 1a) but not during the subsequent 25-day period (P > 0.1, Fig. 1b).

The increased drift of invertebrates may have been due to the increased hydrogen ion concentrations, or to increased aluminum concentrations, or to a combination of both. Schofield has shown that deaths of brook trout in laboratory experiments occur in dilute solutions with a pH of 4.5-5.2 and containing $0.2-1.0~{\rm mg\,I^{-1}}$ aluminum, whereas brook trout survive in pH 4.5-5.0 with $<0.1~{\rm mg\,I^{-1}}$ aluminum. The invertebrates in our study may have been affected in a similar manner $^{19-21}$.

Although loss of chemicals in invertebrate and CPOM fractions was significantly increased with elevated acidity, the total amounts of Al, Ca, C and N in those fractions were small compared with the amounts of these ions in the dissolved form (Table 1). However, if an assessment had been made of chemicals in the biomass of trout, sculpins, salamanders and frogs that left the experimental section during acidification, the estimates of Al, Ca, C, N, P and N lost in the biotic component would have been considerably higher. Thus the loss of biologically bound nutrients such as C, N and P is at a level that could be significant to the stream ecosystem as a whole during acute hydrogen ion stress, as these nutrients would no longer be available for use in the stressed area.

One surprising effect of higher stream acidity was the increased flux of CPOM during the first 5 days (Fig. 1a). The increased loss of CPOM may be due to: (1) a decrease in the number of collector organisms²⁵ (filter- and deposit-feeders)

^{*} Norris Brook, this study.

[†] Headwater streams in the Hubbard Brook Experimental Forest (R. Bilby, personal communication).

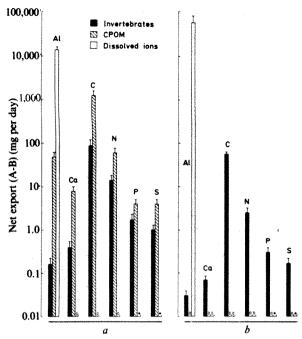

Fig. 1 Mean daily a, acute (5-day) and b, chronic (25-day) effects of elevated hydrogen ion concentration on flux of Al, Ca, C, N, P and S in invertebrates (), CPOM () and dissolved components in Norris Brook (

). Zero designates no change in net flux at site B relative to A. Vertical bars represent standard error. A greater mass was exported from B than A, thus A - B is a negative number. Asterisks indicate that flux of dissolved sulphur and phosphorus, due to elevated acidity, could not be evaluated for the 1977 study; that is, concentrated H2SO4 was added to the stream water to lower the pH and the quality of the dissolved phosphorus data was poor. However, based on preliminary results from an experiment in which HCl was used to lower the pH, no change in dissolved sulphate concentration was detected above and below the experimental addition, and total phosphorus was mobilized in the stream water in the experimental area relative to the reference section.

that use particulate organic matter as food and store it as biomass. In the acidified reach we observed an increase in export of collector and scraper organisms²⁰. Scrapers ingest relatively more periphyton than organic detritus in natural streams^{20,26,2} However, with a decrease in the number of collector organisms, one would also expect an increased loss of FPOM, but the expected loss of FPOM did not occur with the exception of a 25% increase in the net flux of FPOM during the first 3 h after acidification. In addition, we suspect that collectors filter such a small portion of the total water column that increases in FPOM net flux due to decreased filtering (fewer collectors present) may not be detectable. (2) Increased hydrogen ion stress may have caused organisms to move quickly off the bottom or out of accumulations of leaf debris, thus dislodging organic matter and allowing it to be transported downstream by water currents. Based on our quantitative data we believe that the latter factor is more important.

The acute (5-day) results of our acidification experiment may approximate what happens in streams during spring snowmelt in the northeastern US. Hydrogen ions are thought to migrate to the perimeter of snow crystals during the melt-refreeze cycle 16,28,29. It has been reported that as much as 80% of the acidic contaminants in the snowpack may be released in the first 30% of snowmelt²⁹. Depending on rate of melt, soil frost, and other environmental conditions, when an acid-stratified snowpack begins to thaw, these hydrogen ions enter streams and may depress the pH of the water substantially. As the snowmelt period is brief $^{16,17,28-30}$, and because neutralization of hydrogen ions takes place rapidly due to aluminum dissolution reactions in the soil^{31,32} and the streambed (our study) and cation exchange on clay minerals³³⁻³⁵, the period of high acidity may be relatively short and/or limited to headwater tributaries. Our results show, however, that a significant increase in net flux of chemical

components, incorporated in the biomass of organisms and organic matter, occurred within the first 5 days of stream acidification

The 25-day response of the biota to H+ stress may simulate results from chronic acidification from acid rain. An important repercussion of acid precipitation is the elimination of sensitive aquatic organisms²⁰. The reduction in numbers of biotic communities may have important consequences for the budget of organic matter in the headwaters of mountain streams. A greater than normal proportion of detrital material may be used by the decomposer food chain, or transported downstream, or both if detritivores had ingested and temporarily assimilated this organic matter. The altered storage, processing, and export of litter and nutrients may have either beneficial or detrimental effects on the downstream macrobenthos that otherwise would not have been affected directly by upstream acidification.

Because increased burning of coal and other fossil fuels may intensify acid precipitation and deposition in snowpacks, and because low pH values during initial snowmelt periods occur in first-, second- and third-order streams 17, the loss of nutrients, in particular phosphorus and nitrogen, and energy-abundant organic detritus may be of great ecological significance in headwater mountain streams.

This is a contribution to the Hubbard Brook Ecosystem Study. The NSF, the International Paper Company Foundation, and the Environmental Protection Agency, Duluth, provided financial support for the field study at Hubbard Brook. The Northeastern Forest Experiment Station, US Department of Agriculture, Forest Service, Broomall, Pennsylvania, furnished the facilities. We thank B. Bilby for chemical data on CPOM; J. Eaton, B. Wesley and B. Moore for technical assistance, and N. Johnson, C. Driscoll, J. Harte and M. Pratt for critical reviews.

¹³C evidence for dietary habits of prehistoric man in Denmark

Henrik Tauber

Carbon-14 Dating Laboratory, National Museum, Ny Vestergade 10, Copenhagen K, Denmark

Carbon isotopes are fractionated by natural processes such as photosynthetic assimilation of CO₂ and its absorption in water. Carbon fractionation is affected by the type of metabolism used by the plant to fix CO₂ and differs in marine and terrestrial plants. This natural fractionation pattern is passed down the food chain and may therefore be used to elucidate questions on the origin of carbon compounds in nature. Here, the ¹³C fractionation pattern has been used to investigate the dietary habits of prehistoric man in northwestern Europe. The results show that whereas Danish Mesolithic man lived on a diet dominated by sea food, in the Neolithic the human diet consisted predominantly of terrestrial food.

Isotopic fractionation in natural carbonaceous materials relevant to prehistory has recently been analysed $^{1.2}$ and is shown in Fig. 1 as δ ^{13}C values relative to the PDB standard. Due to kinetic effects, terrestrial plants that follow the normal Calvin (C₃) photosynthesis are depleted in the heavy carbon isotopes, as shown by a change in δ ^{13}C values from -6 to -8% in atmospheric CO₂ to ~ -22 to -30% in terrestrial plants ^{13}C content, although with a slight shift towards higher δ ^{13}C values, partly because the respired CO₂ may be enriched in the light isotopes 4 . The magnitude of the fractionation effect in animals may therefore vary both with the nature of the foodstuff and with the position in the natural food chains.

Absorption of CO_2 in water and the subsequent formation of bicarbonate are governed by kinetic effects and by thermodynamic equilibrium processes which lead to an enrichment in the heavy carbon isotopes to $\delta^{13}C$ values close to 0% PDB (Fig. 1). When marine bicarbonate is assimilated during photosynthesis of submerged plants, reaction kinetics again result in a depletion in the heavy isotopes, in this case to $\delta^{13}C$ values of about -10 to -18% and this fractionation is also reflected in marine animals.

This simple isotopic separation between terrestrial and marine plants and animals is partly obscured if Hatch-Slack photosynthesis (C_4) has dominated in the terrestrial plants. Hatch-Slack photosynthesis occurs in several plants growing in arid and subtropical regions, especially in grasses of the family Panicoideae, and leads to δ ¹³C values of between -10 and -18% (ref. 3) (hatched boxes in Fig. 1). The most important cultivated C_4 plants are maize, sugar cane and millet. However, if as in the present study, which concerns temperate northwestern Europe, the influence of C_4 plants can be excluded, the ¹³C fractionation pattern may be used to distinguish between a predominant reliance by man on sea food and terrestrial food^{5,6}. Figure 2 shows the ¹³C content of organic remains of bone

Figure 2 shows the ¹³C content of organic remains of bone collagen or tissue from 28 humans living from 5200 BC to AD 1750, together with ¹⁴C dates of the samples, calibrated according to Clark⁷. Collagen from the bones was isolated as a gelatine by the method by Longin⁸, and the gelatine was converted to CO₂ which was used partly for the ¹⁴C determination in a proportional counter and partly for the ¹³C determination by a mass spectrometric analysis with a reproducibility better than 0.3% and an overall uncertainty of about 0.7%. Samples of human tissues were thoroughly extracted with acids and alkalis to remove extraneous carbon compounds before conversion to CO₂. It was checked that the chemical procedures applied to collagen and tissue samples had only a negligible effect on the isotopic compositions^{6,9}.

The series also included bones of three Eskimos from Greenland whose feeding habits are known or may be safely deduced. Two of these lived at Angmagssalik, East Greenland, before contacts with Europeans, and were therefore forced to subsist almost entirely on sea foods. This is substantiated by the difference between their apparent ¹⁴C age and their historical age, which suggests a 90-95% intake of sea food^{5,6}. The third Eskimo sample was from West Greenland and the difference in ¹⁴C content of human tissue and a reindeer fur, found together, suggests a dietary supply of sea food of about 70% (ref. 6).

The measurements on humans from Denmark proper show a clear distinction between the ¹³C content of humans from Mesolithic time and from the Neolithic and later periods. All six samples from the Danish Mesolithic had a ¹³C content similar to that of the Eskimos from historic times, and thus must represent people with a predominant reliance on sea food, comparable with that in Greenland.

This conclusion is at variance with common archaeological estimates for the period, based on bones and shells found in Mesolithic dwelling places in Denmark, However, fish bones are small and fragile and may easily have been overlooked or under-represented in the early excavations of Mesolithic sites. This is also suggested by a modern excavation of coastal Mesolithic dwelling places at Vedbæk, North Zealand, from where three of the Mesolithic skeletons originate. By a careful sieving of all the excavated materials, several thousand fragments of fish bones were recovered per square metre of the thin cultural layers (ref. 10 and K. Aaris-Sørensen, personal communication). In addition to sea food, high δ^{13} C values in humans may indicate a consumption of fish and birds from streams and lacustrine waters. When comparisons are made with archaeological estimates, it should be remembered that faunal remains from dwelling places often represent consumption during a short or seasonal stay only, whereas the ¹³C content of human bones gives an integrated measure of the composition of the mean food intake over an extended period, probably of the order of 5-10 yr.

All Mesolithic sites shown in Fig. 2 are coastal sites. A strong reliance on sea food therefore seems natural. However, all eight Neolithic skeletons represented in Fig. 2 also originate from sites or graves situated either directly on the coast or within 100–200 m of the sea. These Neolithic people were thus coast dwellers, as were the Mesolithic people, but they did not utilize the resources of the sea to the same extent as did the Mesolithic people. This suggests that a highly developed Neolithic cultural complex, with a different method of subsistence and therefore different food habits, rapidly succeeded a Mesolithic economy.

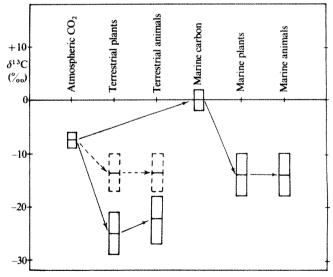

Fig. 1 Fractionation of carbon isotopes in nature. Variations in the ¹³C content are measured as

$$\delta^{13}$$
C = $\left(\frac{^{13}\text{C}/^{12}\text{C sample}}{^{13}\text{C}/^{12}\text{C standard}} - 1\right) \times 1,000\%$

with the Chicago sample of Cretaceous belemnite from the Peedee formation, South Carolina, as a standard.

Fig. 2 ¹³C content of human beings from Denmark and Greenland measured relative to the PDB standard versus calibrated 14C dates of the samples.

With a natural scatter in the δ ¹³C values as indicated in Fig. 1, estimates of the relative proportions of dietary components from δ ¹³C measurements are rather unreliable. It is also uncertain whether part of the isotopic fractionation is influenced by species-related or individual differences in the enzymatic processes during metabolism. It is therefore only concluded that the individuals analysed from the Danish Mesolithic subsisted on a diet dominated by sea food, while those analysed from the Neolithic and later periods lived predominantly on terrestrial food, although in some cases with a significant contribution of marine food.

The number of individuals investigated is rather small, and one should therefore be cautious in drawing far-reaching conclusions about Mesolithic food habits, but the present investigation demonstrates the potential of such measurements for the elucidation of the dietary habits of prehistoric man.

Carbon isotope analysis of separate chemical phases in modern and fossil bone

Charles H. Sullivan* & Harold W. Krueger†

Studies evaluating the distribution of stable carbon isotopes in bone and other tissues of both human and non-human animals have recently been reported1-6. Those investigations which examined the isotopic composition of bone have concentrated on the analysis of bone collagen and demonstrated that the ¹³C/¹²C ratios in bone collagen are directly related to the ¹³C/¹²C ratios of primary photosynthesizing plants in the diets of the animals concerned6-8. With regard to archaeological applications, such analyses have been limited to relatively young samples because of the instability of collagen in bone. We have extended the isotopic method of dietary analysis by using both the organic and inorganic phases of bone with equally good results. In the case of material over a few thousand years old, unless special conditions have preserved collagen, analysis of the organic phase of bone is no longer practical due to its deterioration9. The technique reported here allows dietary analysis of bone over 10,000 years old by using the inorganic phase, which is more stable in fossil material.

Dietary analysis using carbon isotopes is based on the fact that most plants photosynthesize by one of two pathways, the Calvin (C_3) cycle or the Hatch-Slack (C_4) pathway^{10,11}. These pathways produce very different carbon isotope ratios 12,13 which can be readily quantified by standard mass spectrometric techniques. The carbon isotope ratios of animal tissues reflect the proportions of C3 and C4 plants in the animal's diet. Fresh modern bone contains at least three distinct carbon-bearing phases14. Most carbon is in the form of collagen, a complex polypeptide which represents ~10-15% by weight of fresh bone. Hydroxyapatite, also called 'bone apatite', comprises 80-90% by weight of typical bone samples. It contains a small amount of carbon, probably as carbonate ion substitutions for hydroxyl or phosphate ions. A third phase, also inorganic in nature, behaves chemically like a normal carbonate.

The main phases of bone can be separated for isotopic study by appropriate techniques. The 'normal carbonate' phase can be removed and its carbon collected as CO2, by reaction with cold dilute acetic acid under vacuum, leaving the insoluble hydroxyapatite and collagen. After washing to remove acetic acid residues, this material can then be reacted with dilute HCl under vacuum to hydrolyse hydroxyapatite and release its carbon as CO2 for analysis. The collagen remains insoluble and can be filtered off and refined to pure bone gelatin15. Procedures developed for use in radiocarbon dating with kilogram-sized bone samples^{9,16} have been scaled down for isotopic studies of the geochemistry of bone using samples of ≤5 g.

Carbon isotope analyses were performed on CO2 directly evolved from hydroxyapatite, and also on CO2 prepared by a microcombustion procedure from purified bone gelatin-these

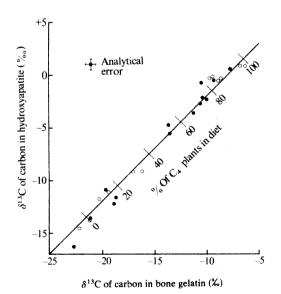

Fig. 1 Relationship between δ^{13} C of carbon in bone gelatin and hydroxyapatite. \bullet , Modern animals; \bigcirc , archaeological or fossil animals.

were done using either Micromass 602D or 903 mass spectrometers (at the Geochron Laboratories). Results are reported in standard δ notation relative to the PDB standard¹⁷.

To examine the relationship between δ^{13} C of bone gelatin and of hydroxyapatite, bone samples were chosen to represent a wide variety of conditions which might affect the isotopic relationships. Several samples were from animal species which are known to have preferences for either C₃ or C₄ plants^{18,19} including species that have dietary inputs of almost pure C₃ or C4. Samples of differing age were analysed to evaluate the isotopic relationship between gelatin and hydroxyapatite as a function of time and to determine what other geochemical interferences, if any, might cause problems. Samples were selected to provide a broad geographical base for the data, including samples from Africa, various sites in North America, and one site in South America. As far as possible, samples from environments with unusual preservation conditions, ranging from the Canadian Arctic to Kenya, New Mexico and the Peruvian desert, were selected. Among the fossil bone samples are several which have very different conditions of burial and preservation.

The analyses of 26 bone samples are given in Table 1 and the data points are shown in Fig. 1 as a plot of δ^{13} C of carbon in hydroxyapatite against δ^{13} C of carbon in gelatin. The analyses in Table 1 are derived from animals having almost the full range of plant diets, from 100% C_3 to 100% C_4 dietary inputs. Vogel et al. ²⁰ have estimated the average isotopic compositions of the basal photosynthetic food webs and assigned δ^{13} C values of -26.5% and -12.5% for C_3 and C_4 plants, respectively. These values represent the total carbon in the plants and may not

accurately represent the carbon that is actually used for metabolism or synthesis of animal tissues. We agree with Tieszen²¹ that there is a need for compound specificity when discussing the minute details of isotopic fractionation. Van der Merwe and Vogel⁶ have determined a δ^{13} C of -21.4% for collagen from North American humans with known C3 diets, and Vogel² reports a value of -21.2% for collagen from African ungulates with pure C₃ diets. Our data for those animals having amost pure C_3 diets indicate a δ^{13} C of ~-21.5%, which confirms the reported shift of $\sim +5\%$ from the basal food web.

Our analyses of gelatin from animals having essentially pure C_4 diets indicate a $\delta^{13}C$ of $\sim -6.5\%$, which is identical to the value given by Vogel² and close to the value of -7.5% calculated by Van der Merwe and Vogel⁶. The analyses of C₄-derived gelatin suggest an isotope enrichment of ~+6% relative to a C4 food source. The difference between the δ^{13} C of C₃-derived gelatin and that of C₄-derived gelatin is ~15% and closely approximates the isotopic difference in the original food materials.

Isotopic analyses of the hydroxyapatite phase of bone are quite different from those of gelatin for the same samples. In all samples the carbon in hydroxyapatite is ~8% heavier than that in the gelatin. Bone apatite derived from pure C_3 diets has a $\delta^{13}C$ of $\sim -13.5\%$ while that derived from pure C₄ diets has a value of $\sim +1\%$. The hydroxyapatite data thus show the same spread of isotopic values as the gelatin data, but exhibit consistently greater ¹³C enrichment relative to diet. While protein synthesis to produce collagen apparently induces an isotopic enrichment of $\sim +5\%$ from the basal food web, the carbon incorporated into hydroxyapatite is consistently enriched by ~+13% relative to the food web. It seems most likely that the carbon contained in hydroxyapatite is derived from dissolved bicarbonate in blood plasma. Analogous isotopic enrichments exist between marine shells and seawater bicarbonate.

Despite the greater isotopic fractionation between diet and hydroxyapatite, it is clear from Fig. 1 that dietary information is accurately reflected. The relationship between δ^{13} C of bone gelatin and δ^{13} C of hydroxyapatite is linear and is approximately represented by the equation $\delta^{13}C_{(apatite)} = \delta^{13}C_{(gelatin)} + 8$. Figure 1 defines a straight line for the data with a slope very close to unity (correlation coefficient = 0.99). This relationship can be used to estimate the percentages of C4 plants in the diet using bone gelatin data, bone apatite data, or both together. The particular value of this relationship derives from the fact that it can be used to gain dietary information, using only hydroxyapatite analyses, from older bone samples which no longer intact collagen. In this case $\delta^{13}C_{(apatite)} =$ contain $\delta^{13}C_{\text{(food web)}} + 13$, and the proportion of C_4 plants in the diet can be obtained directly from the hydroxyapatite axis of Fig. 1.

This model of dietary analysis using bone will have important applications in archaeology, ecology, climatology and other areas and will allow the extension of such studies well back into the Pleistocene.

Mycorrhizal infection and resistance to heavy metal toxicity in Calluna vulgaris

R. Bradley, A. J. Burt & D. J. Read

Department of Botany, University of Sheffield, Sheffield S10 2TN, UK

Although studies of the biology of mycorrhizas have repeatedly demonstrated their capacity to enhance nutrient capture in circumstances where essential elements are present in growth limiting quantities1-3, knowledge of their function in environments containing potentially toxic concentrations of metallic elements is lacking. It is known that mycorrhizal infection can increase the uptake of copper and zinc from soil solutions containing low concentrations of these metals4, but any such increase in circumstances of high metal concentration would clearly be disadvantageous. Because of the large number of situations, both natural and man-made, in which heavy metal toxicity can restrict plant growth, it is of great ecological and applied interest to increase our understanding of those factors which permit growth of plants on heavily contaminated soils. One of the most successful colonists of such soils in northern Europe is the strongly mycorrhizal ericaceous plant Calluna vulgaris5. Calluna has a characteristic 'ericoid' mycorrhizal infection which, in contrast to the situation found in vesiculararbuscular (VA) mycorrhizas, has been shown primarily to enhance nitrogen rather than phosphorus uptake^{6,7}. We have examined the possibility that mycorrhizal infection may influence the resistance of Calluna to high levels of heavy metals. The growth, survival and heavy metal content of two races of Calluna, one from a metal-polluted site and one from an unpolluted natural heathland, have been compared when plants were grown in the mycorrhizal (M) and non-mycorrhizal (NM) condition in sand cultures supplemented with different levels of copper and zinc. We report here that whereas NM plants show no tolerance of these metals at high concentrations, mycorrhizal infection provides a major degree of resistance to the toxicity and that infection leads to significant reduction of the heavy metal content of the shoot.

Calluna seeds were collected from plants growing on heavy metal-contaminated spoil at Parys Mountain, Anglesey, North Wales, and from natural heathland at Stanton Moor, Derbyshire, England. Seedlings of both races were grown aseptically on water agar and then transferred to sterile soil in Petri dishes. Half of the seedlings of each race were inoculated with an isolate of the mycorrhizal fungus Pezizella ericae, which had been obtained from seedlings growing in the original locality of that race. After incubation for 6 weeks in the presence of the appropriate endophyte, M seedlings of both races showed typical heavy endomycorrhizal infection of the ericoid type7. At this stage M and NM plants were transferred to pots of sterile acid-washed sand in which they were supplied with a dilute nutrient solution (1/10th Rorison's)8 containing either copper or zinc, which are the major metallic pollutants at Parys and at several other sites colonized by Calluna in the UK.

The nutrient concentration was selected after preliminary experiments had shown that, with twice weekly addition, macronutrient levels were adequate to sustain growth of both M and NM plants of Calluna, which is an intrinsically slow-growing species. P levels were not, however, high enough to cause inhibition of mycorrhizal infection, or precipitation of added metals. The recoverability of N, P and metals was shown in parallel experiments without plants to be greater than 95% at all treatment levels. In addition, levels of P in this medium were the same as those previously reported as 'extractable' from Parys mine spoil and heathland soil⁵, and were thus considered to be both ecologically and physiologically appropriate for this type of experiment. Copper treatments were at 0, 10, 25, 50 and

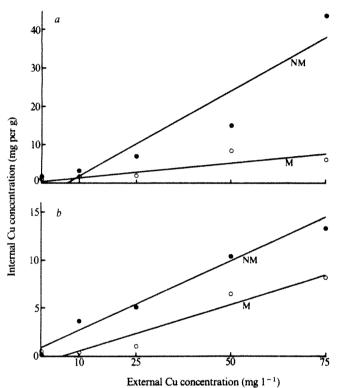

Fig. 1 Copper contents of mycorrhizal (\bigcirc) and non-mycorrhizal (\bigcirc) plants of Parys (a) and Stanton (b) races of Calluna vulgaris together with fitted regression lines showing the overall relationship between the external and shoot concentrations of the metal. In both cases the slopes of the M and NM regression lines differ significantly at P < 0.05.

75 mg l⁻¹ and zinc at 0, 25, 50, 100 and 150 mg l⁻¹. After 12 weeks all seedlings were harvested, their roots and shoots were separated, oven dried, weighed and further processed for analysis of Cu and Zn concentrations by atomic absorption spectrophotometry. The results of the shoot Cu and Zn measurements were subjected to a first order polynomial regression analysis to determine whether external metal concentration influenced tissue concentrations and to compare the magnitudes of any such influence in M and NM plants.

The major response of both races of Calluna to addition of heavy metals was that, with one exception (Calluna Parys, 25 mg l⁻¹ Zn), the NM plants failed to show any growth in the presence of the metals. Growth of both M and NM control plants was vigorous compared with that of NM plants exposed to metals, which indicates that major nutrient deficiencies were not experienced by the plants. M plants, in contrast, showed some growth even at the highest concentrations of metal and in all cases their yields were significantly greater than those of their NM counterparts (Table 1). The main difference between NM plants of the two races was that mortality was somewhat higher in the Stanton plants. Yield differences between M plants of the two races were small and insignificant in the copper treatments, but yields were significantly higher in Parys M plants in the zinc

treatments. This is the most distinctive difference between the races in the M condition. Because neither metals nor nutrients were precipitated at the concentrations used, it is likely that the main treatment effect in the NM plants is directly attributable to the added metal, rather than to interaction between metals and nutrient availability.

Regression analyses applied to the results of shoot copper (Fig. 1a, b) and zinc (Fig. 2a, b) determinations show that NM plants contain significantly higher contents of these metals in all cases except Stanton zinc. Premature death of Stanton NM plants in the Zn treatment probably contributed to the lower accumulation of Zn at the high treatment levels.

At the highest metal concentrations the root systems of NM plants of both races were so poorly developed that they were not suitable for metal analysis. Metal levels in roots of M plants were analysed and were found to be significantly higher than those of the shoots. This suggests that metals are being retained by the mycorrhizal fungus in the roots.

The severity of the growth inhibition in metal-treated NM plants compared with controls, and its association with a marked increase of metal concentration suggest that metal accumulation is primarily responsible for damage. High metal contents in roots relative to shoots of mycorrhizal plants also suggest that the capacity to maintain growth is associated with metal exclusion and hence avoidance of toxicity. It has been shown in

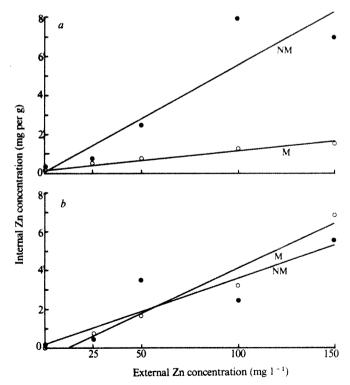

Fig. 2 Zinc contents of M and NM plants of Parys (a) and Stanton (b) races of Calluna vulgaris. Other details as in Fig. 1. The slopes of the M and NM regression lines are significantly different in the Parys race (P < 0.05) but not in the Stanton race.

the case of copper-tolerant races of the grass Agrostis tenuis that the metal is confined to the roots9, the main site of the complexing being the cell wall¹⁰. At high levels of metal, however, inhibition of root extension and hence of complexing ability occurs. In these circumstances the presence of an endomycorrhizal fungal symbiont could be of considerable importance. Fungal cell walls, particularly those of the class Ascomycotina to which Pezizella belongs, are known to have strong affinities for metallic cations11, and the ericoid infection, which provides a much greater concentration of fungal material in the root than that seen in VA mycorrhizas⁷, would be expected to provide a particularly efficient exclusion mechanism. Elaborate hyphal coils occupy most of the cortical cells of Calluna roots in those regions through which absorption occurs and these would provide a greatly increased surface for a retention of metal ions. The capacity, provided by mycorrhizal infection, to avoid metal accumulation may also help to explain the relative success of ericaceous plants on natural heathland soils in which the low pH increases the availability of metallic cations, in particular aluminium and manganese, to levels which are toxic to many non-ericaceous species¹². We are now assessing the ecological and physiological implications of the relationship between mycorrhizal infection and heavy metal resistance in a range of ericaceous species.

We thank Dr R. Hunt for assistance with statistical analysis of the data, Dr A. J. M. Baker for helpful discussions, and the NERC for financial support.

Increased growth of ryegrass exposed to ammonia

D. W. Cowling & D. R. Lockyer

The Grassland Research Institute, Hurley, Maidenhead, Berkshire SL6 5LR, UK

Fluxes of ammonia (NH₃) between the soil/plant system and the atmosphere are components of the nitrogen cycle, but knowledge of them is inadequate 1,2. Grassland in the UK annually receives 8.4×105 tonnes of fertilizer nitrogen3 and 5×105 tonnes of nitrogen through the excreta of grazing ruminants⁴. Emissions of NH₃ from these sources may be 10⁵ tonnes annually and, apart from the loss of a plant nutrient, they may pollute the air. We report here that NH3 has beneficial effects on growth of perennial ryegrass (Lolium perenne L.), apparently through leaf sorption. In air containing NH3 at 16 µg m similar to the level above a grazed pasture⁶, sorption would be 48-224 ng m⁻² leaf area s⁻¹, depending on the density of leaves in the canopy. For grass with a leaf area index of 4, this process would add nitrogen at 6-28 g ha⁻¹ h⁻¹. These results support the suggestion7 that some of the flux of NH3 from soil may be sorbed by overlying plants.

The concentration of NH₃ in the air has been found to decrease with increasing height above the soil within the canopy of a pasture and it was suggested that some NH₃ volatilized from a soil may be sorbed by the overlying plants⁷. Recent studies of a

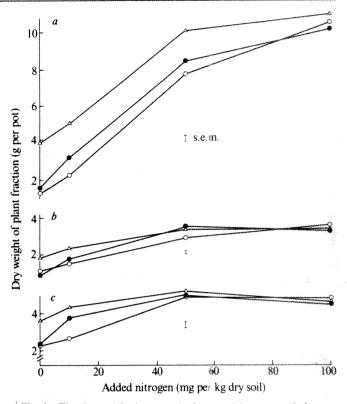

Fig. 1 The dry weight (g per pot) of perennial ryegrass (Lolium perenne L.) cv. S23 harvested in three fractions: a, 'shoots', cut 30 mm above the soil; b, 'stubble', bases of shoots cut to soil level; and c, 'roots' (ash-free basis) recovered by sieving and washing. The plants were exposed to filtered air with NH₃ added to give 11 (\bigcirc), 148 (\blacksquare), and 550 (\triangle) μ g m⁻³ throughout a 16-h photoperiod from day 45 after sowing, when they were first cut to 30 mm, until day 71. Fifteen plants were grown in each 15-cm diameter pot containing 4.2 kg of a sandy loam of pH 7.5, described else-, to which nitrogen (as NH₄NO₃) was added at either 0, 10, 50 or 100 mg kg⁻¹, together with uniform amounts of phosphorus, potassium, sulphur and magnesium (as CaH4 (PO4)2, KH2PO4, K₂SO₄ and MgCl₂). The soil surface was covered with a 10 mm layer of polyethylene granules to minimize sorption of NH3 and evaporation of water. Water was added frequently to the pots to bring the soil to an average tension of 7.4 kPa. Sets of four pots, representing the four rates of added nitrogen, were housed in each of nine chambers which provided three replicates of the three NH₃ concentrations. The chambers, which have been fully described elsewhere ¹⁸, were modified by the removal of the original perforated ceilings, and they received air at 121s⁻¹ to give two air changes per min. In these conditions, the boundary layer resistance to the transfer of water vapour measured just within the leaf canopy was 0.04 s mm⁻¹. The concentration of NH₃ was monitored continually in the outlet air and adjusted daily on the basis of determinations both by UV absorption spectrometry (Lear Siegler SM1000 Ambient Air Monitor, Colorado, USA) and by a colorimetric method using Nessler's reagent

number of species⁸⁻¹² have shown that NH₃ may be sorbed by leaves from air containing 4-14,000 µg m⁻³, sometimes with benefit to yield 8,10. In some studies 12,13, there was no evidence of sorption with NH₃ at $< 4 \mu g m^{-3}$, rather there was release from senescent leaves.

We examined the effects on plant growth of increments in NH₃ concentration and nitrogen supply to the roots (Fig. 1). The weight of shoots increased with NH3 concentration, and increased linearly with the addition of nitrogen to the soil. except at the highest rate. Although the stubble and roots (Fig. 1b, c) responded similarly to the shoots, the effects of the treatments were less clear. The concentration of nitrogen in shoots, stubble and roots (Fig. 2a-c) always increased with NH₃ concentration and with the addition of nitrogen to the soil, except at the lowest rate.

When nitrogen supply to the roots was inadequate, the growth of the plants was enhanced by exposure to NH₃. This

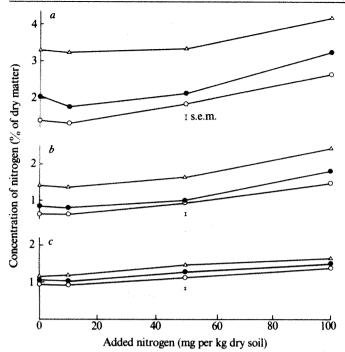

Fig. 2 The concentration of nitrogen (per cent of dry matter) in perennial ryegrass (Lolium perenne L.) cv. S23 harvested in three fractions: a, 'shoots'; b, 'stubble'; and c, 'roots', after exposure to filtered air containing NH₃ at 11 (○), 148 (●) and 550 (△) µg m as described in Fig. 1 legend. The concentration of nitrogen in duplicate oven-dried samples of the three replicate fractions of plant material was determined using an automated Dumas procedure (Coleman 29A Nitrogen Analyser, Illinois, USA).

enhancement was almost certainly through leaf absorption, which has been found for other crops with NH₃ (refs 9, 10) as well as with nitrogen dioxide^{14,15}. The term sorption, as used here, includes absorption into leaf tissue and adsorption on the leaf surface.

The high nitrogen concentration in the shoots exposed to NH₃ at 148 and $550 \,\mu\mathrm{g}\,\mathrm{m}^{-3}$ (Fig. 2a) probably results from leaf sorption of NH₃; sorption by soil and subsequent root uptake was unlikely to have been important 16. The concentration in the shoots of plants grown without added nitrogen and exposed to NH₃ at 11 µg m⁻³ was 1.4%, it increased to 2.6% with the highest rate of added nitrogen but, surprisingly, increased to 3.3% with exposure to NH₃ at 550 µg m⁻³. This comparison was made between the shoots of plants differing greatly in dry weight. A more appropriate comparison may be made by interpolating the shoot weight of plants grown without added nitrogen and exposed to 550 µg m⁻³ NH₃ (that is, 3.97 g per pot) onto the regression line produced for the shoot weight of plants grown with increased added nitrogen but with NH3 at 11 µg m (Fig. 1a). Thus, a similar shoot weight would have been obtained with nitrogen added at 22 mg kg⁻¹ soil; the shoots would have contained 1.5% nitrogen (Fig. 2a), that is, less than half the concentration resulting from exposure to 550 µg m⁻³ NH₃. This suggests that ammonia-nitrogen sorbed by leaves may be less available for transport and metabolism than nitrogen taken up through the roots. Ammonia may have reacted with the leaf surface, or its accumulation may have had both beneficial and injurious effects on growth.

The rate of sorption of NH₃, based on: (1) the leaf area, which was assumed, not unreasonably, to have developed linearly, and (2) the extra nitrogen in plants due to NH₃, may be expressed as a deposition velocity:

$$V_{\rm g}({\rm m~s^{-1}}) = \frac{{\rm rate~of~sorption~of~NH_3~(\mu g~m^{-2}~s^{-1})}}{{\rm concentration~of~NH_3~in~air~(\mu g~m^{-3})}}$$

where NH₃ concentration is reduced by 11 μg m⁻³, to allow for background in the filtered air. This expression is useful for comparing rates of sorption. Velocity ranged from 3 to and was lower for high-yielding plants; a greater 14 mm s

density of leaves presumably increased aerodynamic resistance to NH₃ sorption. In other studies, short-term exposures to NH₃ of isolated plants in chambers have given V_g of 10.4 and 15.4 mm s⁻¹ for two grasses¹¹ and 13.0 mm s⁻¹ for maize⁹.

The sorption of NH₃ by leaves may be important in reducing potential losses to the atmosphere, especially in heavily fertilized, intensively grazed grassland.

We thank Dr L. H. P. Jones for valuable discussion and A. W. Bristow and J. N. Whiteway for technical assistance. The Grassland Research Institute is financed by the Agricultural Research Council.

Sensing of $\Delta \bar{\mu} H^+$ in phototaxis of Halobacterium halobium

V. A. Baryshev, A. N. Glagolev & V. P. Skulachev

Laboratory of Molecular Biology and Bioorganic Chemistry, Moscow State University, Moscow 117234, USSR

Phototaxis in Halobacterium halobium is governed by two distinct photosystems1. Cells are attracted by green light, which is absorbed by bacteriorhodopsin, effectively a light-driven proton pump^{2,3}, and repelled by UV and blue light absorbed by a retinal-dependent pigment and by carotenoids^{1,4-10}. One possibility is that the bacterium detects changes in light intensity directly by the interaction of excited absorbent molecules with the tactile system, in which case the phototactic receptors would be analogous to bacterial chemoreceptors¹¹. However, H. halobium may sense light changes indirectly as changes in the chemical potential of hydrogen ions $(\Delta \tilde{\mu} H^+)^{12,13}$; the coincidence of the action spectra for positive phototaxis and photosynthesis 14,15 indeed support the suggestion that the cells may possess a specific $\Delta \bar{\mu} H^{\dagger}$ receptor, called a 'protometer'. We now describe experiments which indicate that positive phototaxis in H. halobium is governed by $\Delta \bar{\mu} H^+$ sensing, but that negative phototaxis is mediated by a specific photoreceptor system.

Shortly after an increase in blue light intensity, or a decrease in green light intensity, H. halobium cells reverse their direction of travel and, for a certain time period, the rate of reversals remains increased, gradually returning to the basal rate⁸. In peritrichous bacteria (for example, Escherichia coli), the adaptation time to a stimulus is directly proportional to the number of excited receptor molecules¹⁶. In the case of H. halobium the quantitative significance of the adaptation time is unclear and thus the only adequate method of determining taxis is by recording the fraction of cells that respond to a stimulus. Moreover, it seems reasonable to assume that the first reversal is an immediate response to the chemotactic signal, whereas adaptation reflects the process of inhibiting the chemotactic signal transmission. Therefore the first reversal will provide more accurate information about the reception process than the

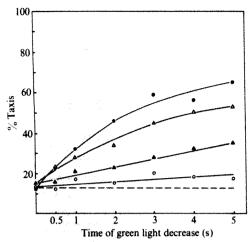

Fig. 1 The effect of inhibiting respiration and ATPase on the sensitivity of *H. halobium* phototaxis. *H. halobium* R₁M₁ lacking gas vacuoles and bacterioruberin (supplied by Dr N. Dencher) were grown in white light at 37 °C on a complex peptone medium (Oxoid) for 96 h. Motility of collected cells was greatly improved by incubation for 24 h in nutrient-free salts media. Cells were observed by phase contrast using a Univar microscope (Reichert). The initial intensity of the green light (500–650 nm) was 9 mW cm⁻². Cell reversal was recorded if the cell reversed within 5 s after insertion of a neutral filter that decreased the intensity by a factor of 1.4. The experimental points are means of 20–60 individual cell recordings. ○, Control; ♠, 0.1 mM DCCD; △, 5 mM KCN; ♠, 0.1 mM DCCD and 5 mM KCN. The baseline indicates the level of spontaneous reversals.

adaptation time. If, during phototaxis, bacteria actually sense changes in $\Delta\bar{\mu}\,H^+$ rather than changes in the concentration of excited bacteriorhodopsin, we would expect the inhibitors of oxidative phosphorylation to increase their sensitivity. Indeed, if the respiratory chain is blocked by CN⁻ and the H⁺-ATPase by DCCD, bacteriorhodopsin remains as the only operating proton pump, and minor changes in light intensity will effect significant changes in $\Delta\bar{\mu}\,H^+$. In the absence of inhibitors the same changes in light, due to the operation of the redox chain, will have little or no effect on the magnitude of $\Delta\bar{\mu}\,H^+$.

There are two ways in which the light stimulus can be varied: by changing the duration of the stimulus, or by altering its magnitude. The first approach was used in the experiment shown in Fig. 1. A given decrease in light was applied to the cell suspension for various periods of time. The sensitivity of phototaxis seemed to be much higher in the presence of CN⁻ and DCCD than in the absence of inhibitors. Oxygen consumption,

Table 1 Responses of H. halobium cells to monochromatic and mixed light

A STATE OF S	Per cent cells reversed	Motility rate
Illumination	in 3 s	$(\mu \text{ s}^{-1})$
Orange background: 0.12 mW	cm ⁻² ,	
$\lambda < 520 \text{ nm}$	<5	1.5
Increase in orange light to		
7.2 mW cm ⁻²	<5	2.7
Orange background + blue ligh	t	
$(\lambda < 400 \text{ nm}), 0.03 \text{ mW cm}^{-3}$	73	1.5
Increase in orange light to		
$7.2 \text{ mW cm}^{-2} + \text{blue light},$		
0.03 mW cm^{-2}	42	2.8
Orange background + intense		
blue ($\lambda < 490 \text{ nm}$)	100	2,7
Increase in orange light to		
$7.2 \text{ mW cm}^{-2} + \text{intense blue}$		
$(\lambda < 490 \text{ nm})$	100	2.7

Cells were incubated in a salt medium with NaCl mainly substituted by KCl^{23} . The slide was kept at 37 °C using a Reichert Biotherm microscopic thermostat. Blue light with $\lambda < 490$ nm (bottom two lines) was saturating for phototaxis.

monitored using a Clark electrode, was completely inhibited by 5 mM CN⁻, and light-driven ATP synthesis measured using firefly luciferase was found to be depressed by 90% in cells preincubated for 30 min with 0.1 mM DCCD (data not shown). In control cells lacking inhibitors a significant taxis response was observed only on a strong decrease in light. We found that the smaller the changes in light intensity, the greater the difference in phototaxis sensitivity between cells in the presence and absence of inhibitors, respectively (Fig. 2a). Control cells showed only a slight response to a twofold decrease in light intensity, while in the presence of inhibitors (closed circles) they responded with an 80% taxis effect.

These data indicate that phototaxis sensitivity strongly increases in conditions in which a sudden decrease in illumination produces a significant change in the energy level. However, the overall phototaxis could result from the mutual action of a protometer and a truly specific bacteriorhodopsin light receptor. A given decrease in light intensity would cause a given drop in the $\Delta \bar{\mu} H^+$ level in cells with inhibitors. A stronger decrease in illumination would result in the same decrease in $\Delta \bar{\mu} H^+$ in the control bacteria. As the decrease in $\Delta \bar{\mu} H^+$ is the same in both cases, although the changes in light intensity differ, an equal phototaxis response would rule out a specific photoreceptor mechanism. If the phototaxis activity were higher in the strongly illuminated sample, that is, in that lacking inhibitors, this would suggest a specific light-sensing process.

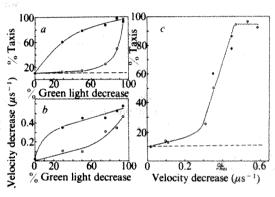

Fig. 2 a, The correlation between taxis activity and changes in motility rate with decreases in illumination. Conditions essentially as described for Fig. 1 legend. Initial intensity of the green light (500-650 nm) was 9 mW cm⁻². Reversals were recorded after the insertion of various neutral filters for 5 s: ○, control; ♠, 0.1 mM DCCD + 5 mM KCN. b, Motility rate was recorded by means of an ocular scale and a stopwatch before and after insertion of the same neutral filters as were used in a. The ordinate is the difference between control motility rate (2.4 μ s⁻¹) and motility rate after a decrease in light: ○, control; ♠, 0.1 mM DCCD + 5 mM KCN. c, Plot combining the data from experiments a and b.

As bacterial motility was found to be directly supported by $\Delta \bar{\mu} \, H^+$ (refs 17–20) and its rate to be positively correlated with the magnitude of $\Delta \bar{\mu} \, H^+$, we used motility rate as a probe for $\Delta \bar{\mu} \, H^+$. Figure 2 shows results of an experiment in which both motility rate and taxis were studied as a function of light intensity. When the phototactic response was plotted against the decrease in swimming velocity (Fig. 2c), the experimental points obtained both with control cells and those with inhibitors all lay on the same curve. This means that differences in light intensity changes per se are non-essential and that phototaxis is governed by changes in the energy level, presumably by $\Delta \bar{\mu} \, H^+$.

It seems to be important to correlate phototactic response with the absolute values of changes in $\Delta \bar{\mu} H^+$, although it is technically difficult to measure $\Delta \bar{\mu} H^+$ both rapidly and quantitatively in H. halobium in given conditions. Experiments on this are being done.

One may think that ATP, not $\Delta \bar{\mu} H^+$, is the principal effector in phototaxis. The possible existence of a specific ATP receptor in enterobacteria has been discussed elsewhere ¹³. However, this is not the case in *H. halobium*, as the addition of DCCD

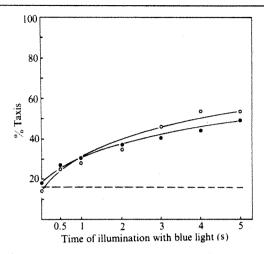

Fig. 3 The effect of inhibiting respiration and ATPase on the avoidance of blue light. Conditions were essentially as described in Fig. 1 legend. The intensity of the green background (500-580 nm) illumination was 36 mW cm^{-2} . Blue light stimuli ($\lambda < 400 \text{ nm}$, $1.4 \times 10^{-2} \,\mathrm{mW \, cm^{-2}})$ were applied through an incident light illuminator of the Univar microscope equipped with a 200-W mercury arc.

increased, rather than inhibited, the sensitivity of the phototaxis

The approach used in studying positive phototaxis was applied to test the negative phototaxis system. Blue light is known to affect the bacteriorhodopsin photocycle and thus to decrease $\Delta \bar{\mu} H^+$ (ref. 21). Wagner et al.²² found that UV light (360 nm) partially inhibited K⁺ uptake by H. halobium cells. They speculated that the behavioural response to blue light might be due to a decrease in membrane potential²². However, the inhibiting action of blue light, with a maximum at 412 nm, cannot be solely responsible for negative phototaxis, which has two main maxima, at 280 and 370 mm¹. Dencher³ and Hildebrand6 suggested that the blue light acts by decreasing the membrane potential, opening an ion channel associated with the pigment P₃₇₀. If the repelling action of blue light were indeed due to a decrease in $\Delta \bar{\mu} H^+$, one would expect the sensitivity of phototaxis to depend on the activity of the cellular proton pumps and it should thus be increased by CN and DCCD

Pulses of blue light with durations varying from 0.5 to 5 s were applied to cell suspensions with and without CN and DCCD (Fig. 3). Avoidance of blue light did not show a dependence on the ability of the stimulus to change the energy level. To test further the possible dependence of negative phototaxis on changes in $\Delta \bar{\mu} \, H^+$, a simultaneous stimulation by blue and green light was used; effects were shown to sum up algebraically⁸. Cells were partially de-energized by preincubation in dim light. As the K^+ gradient may support the energization²³ and motility²⁴ in H. halobium cells for a prolonged period of time, bacteria were incubated in a medium with a high KCl concentration. After incubation for 2 min the motility rate decreased from 2.7 to 1.5 μ s⁻¹ and could be brought to the initial level by illuminating the suspension with intense light for 10 s (Table 1). A mixture of blue and orange light elicited a reversal of 42% of H. halobium cells in 3 s. This reversal was accompanied by a significant increase in the motility rate, indicating that the repellent response of the cells to blue light is not due to a decrease in $\Delta \bar{\mu} H^{+}$. Increase in blue light alone produced 73% reversal of cells, which indicates that the effect of mixed light was a summation of an attractant (orange) and repellent (blue). Blue light alone had no effect on motility rate. The increase in motility rate was the same whether the intensity of orange light was increased alone or in combination with blue. If a high intensity blue light was used, the rate of reversals became independent of a simultaneous increase in orange light. The data shown in Table 1 clearly demonstrate that negative phototaxis does not result from changes in $\Delta \bar{\mu} H^{+}$.

The differences in the mechanisms of positive and negative phototaxis in H. halobium, that is, an indirect sensing of green light by means of a protometer and a direct sensing of blue light by a specified photoreceptor, would explain the striking differences in light sensitivity. Blue and UV light evoke a response at 1/10 and 1/500 the intensity of green light¹. This difference seems to be natural if we consider that the more sensitive system operates as a specialized photoreceptor.

Control of mucus hydration as a Donnan equilibrium process

Patrick Y. Tam & Pedro Verdugo*

Center for Bioengineering and Department of Biological Structure, University of Washington WD-12, Seattle, Washington 98195, USA

The physical properties of the mucus secreted by the uterine cervix of primates and other animals undergo periodic changes which are important in the regulation of fertility. During the luteal phase of the sexual cycle, cervical mucus is thick, rubbery and impenetrable by spermatozoa; by the time of ovulation, it is a watery gel easily penetrated by spermatozoa. Although these changes in the rheological properties of mucus have been attributed to variations in the covalent cross-linking between long chains of glycoproteins, the main macromolecular constituent of cervical mucus^{1,2}, recent studies^{3,4} suggest that the macromolecular matrix of cervical mucus is probably not covalently crosslinked. Rather it is an entangled random network of long mucins3, in which case the observed changes in the physical properties of mucus would be explained by varying degrees of hydration, the mechanism of which is not understood5. We now describe experiments which show that the hydration of cervical mucus may be controlled by a Donnan equilibrium process.

Polyionic gels can behave as a semi-permeable membrane and become hydrated following a Donnan equilibrium. As mucins are polyionic species, mucus hydration could also follow a Donnan equilibrium in which the glycoproteins may function both as structural components of a stable continuous network, analogous to a semi-permeable membrane (which prevents the movement of polyions), and as the entrapped polyionic species that generate the osmotic drive. A typical feature of Donnan equilibria is the dependence of the movement of water on the ionic concentration and pH of the solvent. As the transport of ions in mucus secretory epithelia is known to be physiologically regulated5, it seems reasonable to propose that if mucus swelling follows a Donnan equilibrium, mucus hydration could be phy-

^{*} To whom correspondence should be addressed.

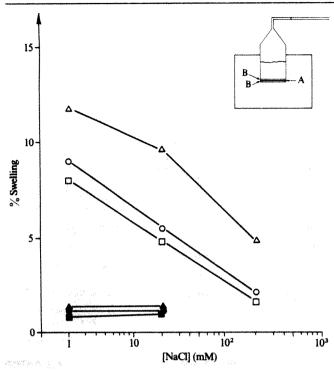

Fig. 1 Relationship between relative (%) swelling of cow cervical mucus at pH 7 and NaCl concentration in the swelling medium for three different samples of luteal (open symbols) and three samples of oestrous mucus (solid symbols). The inset is a diagram of the swelling chamber. Exchange of H_2O , ions and low molecular weight species is established across the Nucleopore filter membrane (A), which is sandwiched between two washers made of stainless steel fine wire mesh (B). See text for more detailed description.

siologically regulated by movement of water and electrolytes (including \mathbf{H}^+) across the epithelia.

Six samples each of luteal and oestrous fresh cow cervical mucus were obtained from the Animal Research Facility of Carnation Farms in Washington. The stages of the oestrous cycle were determined by rectal palpation. Mucus swelling was measured as the relative volume expansion of mucus, using an osmometer-like swelling chamber (Fig. 1 inset). In this chamber 0.1 ml of mucus sits on a diaphragm of Nucleopore filter (0.8 µm pore size) at the bottom of a small cylindrical container. The upper portion of the cylindrical container, above the mucus, is filled with silicone oil, forming a single fluid column that ends in a capillary tube (10 cm long and 16.7 µl volume). The water transfer between the mucus and the swelling solution is established across the filter and the volume expansion of the mucus is measured by the displacement of the oil meniscus in the capillary tube. In these experiments, the bottom of the mucus container was immersed in 50 ml of swelling medium which was continuously agitated at room temperature. Swelling medium was a water salt solution containing 2, 20 or 200 mM NaCl at neutral pH, or 150 mM NaCl at pH 8.0, 7.6, 6.99 or 6.46. The pH was adjusted with a phosphate buffer by changing the ratio of monobasic to dibasic sodium phosphate, but keeping the total phosphate concentration constant at 5 mM.

Figure 2b shows the typical time course of swelling of oestrous and luteal mucus in a swelling solution containing 150 mM NaCl at pH 6.46. Note that oestrous mucus demonstrates a very small amount of swelling whereas luteal mucus allows a 13% swelling at equilibrium in ~ 200 min. Figures 1 and 2 show the relationship between swelling at final equilibrium and salt concentration, and swelling and pH, respectively, in both oestrous and luteal mucus. Whereas oestrous mucus does not undergo swelling, luteal mucus demonstrates significant and irreversible swelling inversely proportional to the \log [NaCl] in the swelling medium, and at constant salt concentration (150 mM NaCl), linearly proportional to the pH of the swelling solution.

A unique feature of the Donnan equilibrium is the redistribution of water and ions in the presence of a barrier that limits the mobility of an electrostatically charged (polyionic) molecule. In the most common experimental demonstration of a Donnan equilibrium, this barrier is a semipermeable membrane? However, there are other ways of hindering the mobility of a polyionic molecule. For example, in polyionic gels the mobility of an electrostatically active polymer is limited by topological constraints (cross-links and/or entanglements) between long chains of the polymer itself. In the particular case of the mucus, the topological constraints of the molecular matrix prevent the glycoproteins from diffusing out of the gel. Therefore, in mucus, glycoproteins have a dual role as the structural elements of the entrapping molecular network, and as the entrapped polyions responsible for the osmotic drive.

The dependence of the movement of water on the concentration of ions and the pH of the solvent is a typical characteristic of a Donnan equilibrium and is due to the interaction of polyionic species. The phenomenon can be easily visualized by considering the glycoproteins as electrostatically charged chains. Although the role of ions in water movement depends on their colligative effects, pH affects water movement by changing the total electrostatic charge of the entire chain in a way that is

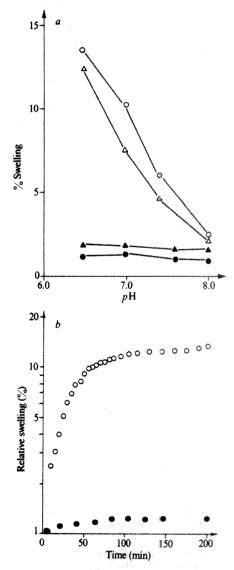

Fig. 2 a, Relationship between relative (%) swelling of cow cervical mucus and pH, in a swelling medium containing 150 mM NaCl. Samples ○, △ are luteal, and ▲, ● are oestrous mucus. b, Time course of swelling as relative (%) volume increase for oestrous (●) and luteal (○) cow cervical mucus in a medium containing NaCl 150 mM, pH 5.46, at 20 °C.

dependent on the ionization constant of dissociable groups in the glycoproteins. The dominant dissociable groups in mucus glycoproteins are axial sialic acidic groups in the oligosaccharide side chains of the molecule⁸. Therefore, the decrease in mucus hydration with increasing pH and/or ionic concentration found in these experiments is indeed predicted by the Donnan equilibrium.

The rheological properties of mucus are important in transcervical migration of sperm into the uterus as well as in mucociliary transport in the airways. Hydration of mucus is a critical determinant of these properties9. Mucus is discharged from the secretory granules of the cell as densely packed, membrane-free boluses 10 which are then hydrated in some unknown way 5. The evidence presented here shows that luteal cow cervical mucus can be hydrated according to the Donnan equilibrium. Within this equilibrium, the changes of pH and salt concentration that effectively control mucus swelling in vitro are in the same range of physiological values reported in cervical mucus of cows and women. Although the actual fluctuations of NaCl in cervical mucus remain a controversial issue^{11,12}, there are indications that the onset of mucus hydration (and ferning formation) is preceded by a decrease in pH which also coincides with the earliest increases in urinary oestrogens 13,14

These findings, together with our previous observations³, point to a new concept in understanding the physiological control of mucus hydration and rheological properties. They predict that mucus boluses consisting of densely packed entanglements of mucins could be swollen in the extracellular medium following a Donnan equilibrium process. Accordingly, the movement of ions (including H⁺), soluble proteins and water across the mucosa, as well as the amount of soluble proteins and ions within the secreted mucus, could be the variables under physiological control which would determine mucus hydration, and thereby its rheological properties. It has been shown that secretions of soluble proteins in the cervix¹⁵ and uterus are responsive to hormonal control (M. K. Postle and R. B. Heap, personal communication). However, the role of the soluble proteins found in the mucus has not been clearly established 15,16 The model we propose suggests an osmotic function for the soluble proteins as potentially entrapped polyions and is consistent with the available evidence, that 'unswollen' luteal mucus contains high amounts of soluble proteins, while hydrated oestrous mucus contains small amounts¹⁵. In the latter case, the mucus molecular network would be expanded allowing soluble proteins to undergo further dilution and escape the gel matrix.

Although there is no direct evidence to validate the predicted hormonal or neurohormonal control of the movement of water, H⁺ and electrolytes across the cervical mucosa, it has been shown that in the respiratory mucosa the movement of water, Na+ and Cl- is responsive to hormonal or neurohormonal

The present experiments were limited to an exploration of the interaction of cow cervical mucus with NaCl at different pH. However, with only minor constraints, the concept that mucus hydration could be regulated by the Donnan equilibrium remains valid for other types of mucus and other ionic influences. For instance, an interesting implication of this concept is the potential existence of a Donnan-equilibriumcoupled system to delay enzymatic catalysis. Indeed, the application of synthetic polymer gels to entrap enzymes (including proteases) is well known in engineering 17 and is beginning to find wide industrial application.

Another significant prediction of the proposed model regards the pathophysiology of cystic fibrosis, where mucus would be permanently unswollen probably due to deficiencies in the control of the swelling medium and/or the polyionic composition of the secreted mucus. Although there is no direct evidence for defective trans-epithelial movement of water and ions in cystic fibrosis, it has been shown that NaCl is markedly increased in exocrine sweat, and that calcium transport seems to be decreased in red cells and fibroblasts and increased in exocrine secretions in these patients 18-20.

The fate of inner cell mass and trophectoderm nuclei transplanted to fertilized mouse eggs

Jacek A. Modlinski*

MRC Mammalian Development Unit, 4 Stephenson Way, London NW1 2HE, UK

When nuclei from 12-18-cell mouse embryos have been injected into fertilized mouse eggs^{1,2}, donor and host chromosomes in those eggs that survived the operation combined to form a single tetraploid nucleus. Some of the resulting embryos developed into morphologically normal blastocysts. At the 8-cell stage, mouse blastomeres are still totipotent3 and are indistinguishable from one another. By the blastocyst stage, inner cell mass and trophectoderm have separated into distinct cell lineages that differ in morphology, physiology and biochemistry. The fetus develops entirely from inner cell mass while the trophectoderm contributes only to placenta and fetal membranes; it is unclear when this is determined. Aggregation experiments suggest that some blastomeres are still labile at the late morula/early blastocyst stage^{6,7}. If this was the case at least some of the donor cells used in my previous nuclear transfers might have been still totipotent. However I report here that nuclei from trophoblast and inner cell mass are different from one another, as judged by the developmental fate of fertilized mouse eggs to which they are transplanted.

Fertilized one-cell eggs were obtained from spontaneously ovulating CR and Q females mated with syngeneic males. Eggs were collected between 10.00 and 12.00 h on the day of mating. Donor cells were from 3.5-4-day old CR, Q and MF1 blastocysts from which the zona pellucida had been removed by pronase. The mural trophectoderm was dissected from the blastocysts microsurgically8; inner cell mass tissue was obtained by either microsurgery or immunosurgery9. The severed mural trophectoderm and inner cell mass tissues were placed for $\sim 30-40$ min in Ca²⁺- and Mg²⁺-free phosphate-buffered saline (a 0.02% solution of EDTA was occasionally also used) and pipetted using a narrow pipette. Single cells taken from the

^{*} Present address: Institute of Zoology, University of Warsaw, Warsaw, Poland

trophectoderm or inner cell mass were drawn into a fine glass micropipette to disrupt the cell membrane; the nucleus and the associated cytoplasm were then injected into fertilized eggs at the early pronuclear stage 1.2. Before and during the operation the host eggs were kept in medium 16 (ref. 10) containing 10 g ml⁻¹ cytochalasin B to facilitate microsurgery^{11,12}. The eggs which survived the operation were cultured in medium 16 for 48-90 h and most of the resulting embryos were examined in air-dried preparations13

Trophectoderm and inner cell mass nuclei looked intact and were similar in appearance at the time of injection, and therefore there was no reason to believe that trophectoderm nuclei suffered more damage than inner cell mass nuclei during recovery; the proportion of eggs degenerating immediately after injection was similar after transplanting either type of nucleus. However, Table 1 shows that the fate of the two classes of eggs was different. Eggs that had received inner cell mass nuclei developed similarly to those injected with morula cell nuclei2. Of the 16 that were cleaved, eight developed to the late morula and blastocyst stage, and appeared normal. In six embryos (one blastocyst, two morulae, one 4-cell and two 6-cell embryos), tetraploid metaphase plates were found. This shows that nuclei originating from these two types of cells (that is, morula and inner cell mass nuclei) can contribute their chromosomes to those of an egg, thus both sets can form a common metaphase plate. The embryo carrying such a tetraploid hybrid nucleus can develop at least to the blastocyst stage. Thus, although the degree of activity of the transferred genome is unknown, one may suppose that the nuclei of such cells do not change irreversibly (if they do so at all) during preimplantation development and their redifferentiation is possible in the egg cytoplasm. In contrast, when the donor nuclei were trophectodermal in origin, donor and host chromosomes still integrated into a single nucleus but development was arrested after two to three cleavages, and no late morulae or blastocysts were formed.

The failure of trophectodermal nuclei to support normal development agrees with the recent findings of Illmensee and Hoppe¹⁴. Mouse eggs enucleated after fertilization and injected with inner cell mass nuclei developed not only into normal blastocysts but, after transfer to pseudo-pregnant foster mothers, into normal fertile mice. In contrast, eggs which received trophectoderm nuclei never developed beyond the first few cleavage divisions.

One of the characteristics of mural trophectoderm (that is, that part of trophectoderm not overlying the inner cell mass) is that it undergoes little or no further cell divisions after the blastocyst stage. DNA accumulation continues by a process of endoreduplication¹⁵, resulting in trophoblast giant cells with large nuclei that may contain several hundred times the haploid DNA content. To determine whether endoreduplication occurred after injection of trophectoderm nuclei into fertilized eggs, the embryos arrested in cleavage (see Table 1) were fixed, air-dried and stained with Feulgen, together with a control series of embryos recovered from the uterus on the fourth day of gestation; DNA determinations were then carried out on the nuclei of experimental and control embryos by microdensitometry. There was no evidence of endoreduplication

Trophectoderm nuclear transfer	r 4	6.5	1	10	6	9	26
Control	7	32.7	60	62	0	2	124

Embryos were fixed and air-dried; a cut surface of the mouse liver was pressed on to the end of the slide, and then Feulgen-stained. DNA determinations were made using an M85 Vickers integrating microdensitometer. Liver nuclei gave discrete peaks for 2C, 4C, 8C, 16C, and 32C DNA values, where C is the haploid DNA content; embryo nuclei were assessed against these standards. In the experimental series, each nucleus was measured three to four times; the readings obtained were very consistent. In the control series, where cell number was greater, some nuclei overlapped and were therefore not measured.

(Table 2): the DNA contents of the nuclei were in the 4-8 C (where C is the haploid DNA content) range expected in tetraploid cells arrested in the G₁ or G₂ stage of the cell cycle, respectively, while the diploid controls were almost all in the 2-4 C range.

Although the transplanted trophectoderm nuclei did not undergo endoreduplication as they would during normal development, the observation that cleavage in this series was arrested after two or three cell divisions suggests that these nuclei not only have a restricted potential for further division themselves, but that, following their own programme, they may impose it on the host cell and block its divisions as well. Alternatively, some factor in the trophectoderm cytoplasm, which in this technique is injected into the fertilized egg along with the donor nucleus, may inhibit fur her development. Also, the lack of endoreduplication in such embryos might be the result of the influence of egg cytoplasm. Thus it is likely that the behaviour of trophectoderm transplants is the result of complicated interactions between host and donor nuclei and cytoplasm.

In Amphibia, nuclei even from differentiated cells have, after transplantation to enucleated eggs, been able to support development up to the late tadpole stage, which consists of a wide variety of differentiated tissues 16. The present observation does not necessarily indicate any difference between Amphibia and mammals. Trophectoderm is a highly specialized tissue, with a limited lifespan¹⁷ and no share in forming the embryo itself. It may be that nuclei from tissues differentiated within the embryo will prove better able to participate in normal development.

I thank Dr Peter Barlow for allowing the use of his microdensitometer, and Drs Mia Buehr and Anne McLaren for Feulgen staining and ploidy determinations, respectively. I also thank Dr McLaren for helpful suggestions in preparation of the manuscript, and EMBO for a Fellowship and the MRC Mammalian Development Unit for laboratory facilities.

Dendritic territories of cat retinal ganglion cells

H. Wässle*‡, L. Peichl*‡ & B. B. Boycott†

- * Friedrich-Miescher-Laboratorium der Max-Planck-Gesellschaft, Spemannstrasse 37, D-7400 Tübingen, FRG
- † Medical Research Council Cell Biophysics Unit, King's College, 26-29 Drury Lane, London WC2B 5RL, UK

Ganglion cells have to cover the retina with their dendritic fields so that every point of the visual space is 'seen' by at least one ganglion cell of each physiological type. Using neurofibrillar methods it has now become possible to stain all the α -ganglion cells so that their dendritic network can be analysed¹. Both subpopulations of α -cells, corresponding physiologically to ON-brisk-transient cells²-5 and OFF-brisk-transient cells, achieve a uniform and independent coverage of the retina. The cell bodies are arrayed in a regular mosaic¹. δ and the dendritic fields adapt to the available space. It is suggested that during development interaction between neighbouring ganglion cells of the same functional type regulates their dendritic field sizes.

There are more or less economical ways in which nerve cells can overlay a planar surface with their dendrites, given the requirement that every point should be covered by at least one dendritic field. For cells arrayed in a hexagonal or square lattice with spacing 'a', circular dendritic fields of radius $a/\sqrt{3}$ or $a/\sqrt{2}$ would provide at least onefold coverage (Fig. 1). Were the cells distributed at random, onefold coverage could be achieved either by rather large dendritic fields of uniform size or by interaction between neighbouring cells, where adjustment of the dendritic field size to the local intercellular separation would give rise to a broad and irregular range of dendritic fields.

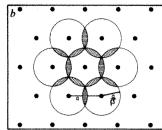

Fig. 1 a, Square lattice of cell bodies. The smallest circular dendritic fields, which would provide a onefold coverage, have a radius of $a/\sqrt{2}$. In the hatched area the dendrites of two cells overlap. b, Hexagonal array of cell bodies. In this instance at least onefold coverage is ensured by dendritic fields of radius $a/\sqrt{3}$.

Ganglion cells of the retina are a good model system for study of the organization of such a sheet of neurones because their cell bodies and their dendritic fields approximate to a single plane. In the cat retina several different morphological 7 and physiological classes 8 of ganglion cells have been defined. With neurofibrillar staining methods all α -ganglion cells were stained to their whole extent, that is, cell body and dendritic tree 1 . It was shown that for all OFF-centre cells the dendritic branches lie close to the inner nuclear layer, whereas for ON-centre cells the branching plane is $\sim\!10~\mu\mathrm{m}$ closer to the ganglion cell layer $^{1.9}$. This then constitutes a functionally homogeneous population of neurones which is accessible to quantitative investigation.

Figure 2a isolates the ON-population of α -cells and shows the field homogeneously covered by the dendrites. That the cell bodies are distributed nonrandomly was shown by analysis of their nearest-neighbour distribution, which is gaussian^{1,6}. The degree of dendritic overlap is rather small; an area centred on

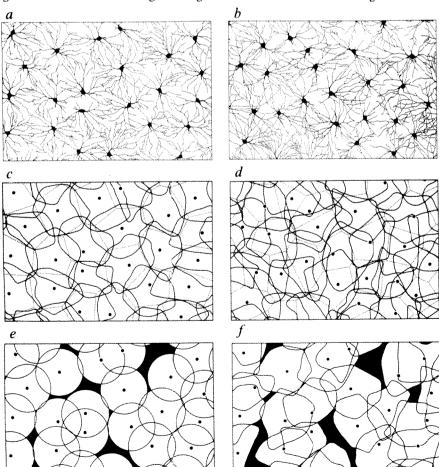

Fig. 2 a, The population of $ON-\alpha$ -ganglion cells taken from an area 1.7×1.2 mm of a Bodian-stained cat retinal whole mount (eccentricity 4 mm). b, Same field as in a, but only the OFF- α -ganglion cells are shown. c, Solid curves are the contours of the dendritic fields of the ON- α -cells shown in a and the dots indicate the cell body locations. The dotted polygons are Dirichlet domains, which were constructed for each cell body as described in the text. d, Same diagram as in c but for the OFF- α -cells. e, Coverage of the retina with hypothetical circular dendritic fields based on the mosaic of $ON-\alpha$ -cells; the black areas are not covered. f, Every ON-α-cell dendritic field is substituted by its right-left mirror image with the cell body unchanged.

‡ Present address: Max-Planck-Institut f
ür H
örnforschung, Deutschordenstr. 46, D-6000 Frankfurt/M, 71, FRG.

the cell body of each neurone is not covered by the dendrites of neighbours. OFF-cells show the same arrangement (Fig. 2b). Dendritic fields were defined by connecting the outermost dendritic tips of every cell by a smooth closed curve (Fig. 2c, d). The dendritic fields are irregular. In some cases there is an apparent correlation between the dendritic tree of a cell and the space not occupied by neighbours.

The concept of Dirichlet domains¹⁰, which cover the area by contiguous convex polygons, is introduced in Fig. 2c and d for comparison. Around every cell body a circle of 500 µm diameter was constructed and the intersecting lines of neighbouring circles were drawn. Dirichlet domains subdivide the area into small territories, one for each cell, with the property that every point in a given territory is closer to its own cell body than to any other. Thus, a dendritic growth model in which the dendrites grow out of the cell bodies at the same time and rate and stop growing when they touch dendrites of neighbouring cells can be described in terms of Dirichlet domains, although they do not account for overlapping dendritic trees. The Dirichlet domains are a rather good approximation to the dendritic fields. Basic features, such as the orientation of the long axis, nearly always agree as between the dendritic field and its Dirichlet domain. This implies that there might be some mechanism of mutual regulation of the dendritic growth of neighbouring ganglion cells of the same type.

Another test for the correlation between the dendritic field dimensions and the available space is shown in Fig. 2e. Circular fields of the average dendritic field diameter (399 µm) were constructed around each ON-cell perikaryon. Such uniform domains leave gaps and the coverage is consequently incomplete and not very homogeneous (Fig. 2e). When, with the cell body in its original position, every dendritic field is replaced by its mirror image, the coverage is again very inhomogeneous, uncovered gaps are found next to areas where the dendritic fields of several ganglion cells overlap (Fig. 2f).

We infer from these observations that some kind of local regulation which defines the shape and size of the dendritic fields must prevail during development. This process must be highly specific because ON-centre cells influence neighbouring ONcentre cells but not OFF-centre cells and vice versa. The same mechanism could regulate the increase of the average dendritic field size with distance from the central area and so balance the decreasing α -cell density. A similarly specific process must be active at the cell body level to regulate nearest-neighbour distances1.

Every point in the field represented by Fig. 2c is covered by an average of 1.4 ON- α -cells (average dendritic field area \times density). For cells arrayed in a square lattice with circular dendritic fields, the geometrical constraints shown in Fig. 1a lead to an average coverage of 1.57 to ensure at least a onefold coverage everywhere. Arrangement of the ganglion cells in a hexagonal lattice would require an average coverage of 1.21. This shows that although the ganglion cells are in fact distributed less precisely than in a perfect lattice, their dendritic trees cover the given field of Fig. 2a more economically than in a square array and close to the theoretical limit possible in a hexagonal lattice.

The size and shape of an α -cell's receptive field centre, although slightly larger, closely corresponds to its dendritic field³. Therefore, these morphological results imply a complete and economical coverage of either functional subclass. Twodimensional sheets of neurones are not only found in the retina; arrangement in layers is common in many parts of the central nervous system. The multilamellar structure of the cerebral cortex is an example and it would be interesting to see whether identical functional units there exhibit the same kinds of territorial attributes and regular intercell spacings.

Androgen increases formation of behaviourally effective oestrogen in dove brain

Th. Steimer* & J. B. Hutchison

MRC Unit on the Development and Integration of Behaviour, University Sub-Department of Animal Behaviour, Madingley, Cambridge CB3 8AA, UK

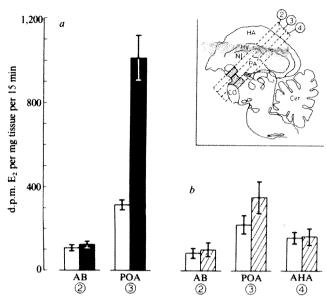

Oestradiol-17ß (E2) formed from testosterone in the brain is thought to be involved in the hormonal control of male sexual behaviour in some mammal species 1-3. In the male dove, Streptopelia risoria, the aromatase system in the preoptic area (POA) is very active in converting testosterone to E2 (ref. 4). This oestrogenic metabolite has specific effects on male nest-orientated courtship patterns, which are mediated by an oestrogensensitive system in the preoptic-anterior hypothalamic area of the brain⁵. The preoptic aromatase system is likely to be important in the regulation of androgen action on male courtship behaviour, as no circulating oestrogen can be detected in the blood plasma of the male⁶. We report here that the level of aromatase activity in the POA depends on androgenic stimulation. Conversion of testosterone to E2 is markedly increased in castrated males injected intramuscularly (i.m.) with testosterone propionate (TP). Increased aromatase activity seems to be due to induction of the enzyme and is specific to the POA These findings indicate that the formation of behaviourally effective oestrogen in a specific brain target area is under hormonal control and suggest a role for this regulatory mechanism in the integration of courtship behaviour in the male dove.

The brain system underlying nest-soliciting display in the male dove can be activated in short-term castrates by either testosterone or E₂ (ref. 7). However, while E₂ effectively restores nest-soliciting to pre-castration levels in long-term castrates, testosterone is virtually ineffective8, suggesting that capacity for aromatization declines with long-term androgen deficit. Prolonged treatment with TP increases nest-soliciting display to some extent in long-term castrates, suggesting that aromatase activity might increase due to the action of androgen⁸. Here we examine the possibility that androgen influences the preoptic aromatase system to increase the formation of E2.

In experiment 1, aromatization of testosterone was measured using a previously described microassay. Two groups of birds (n = 8 for each group) were castrated and 30 days later they were injected on 12 successive days either with androgen or avian saline according to previously described procedures⁷. The dose of androgen (300 µg TP in 0.3 ml avian saline) used is known to induce nest-soliciting behaviour in 30-day castrates⁷. Males were tested daily for courtship⁷ and nest-soliciting behaviour was restored to pre-castration levels in the TP-treated group. Two brain areas were examined, the POA and a non-androgen target area, the area basalis (AB). Aromatase activity in the TP-treated group was increased about threefold as compared to control levels (Fig. 1a). This difference was highly significant (P < 0.001, Student's t-test). Aromatase activity was not affected in the AB, which is immediately adjacent to the POA but is not an androgen target area and shows much lower rates of testosterone conversion4

To determine whether the effect of TP on aromatase activity is dose-dependent, a lower dose (30 µg per day) and shorter

^{*} Present address: Département de Biochimie Médicale, Ceatre Médical Universitaire, 1 rue Michel-Servet, CH-1211 Genève, Switzerland

a, Experiment 1: aromatase activity was markedly increased (P < 0.001, Student's t-test) in the POA of short-term castrates injected i.m. for 12 days with 300 µg per day of TP (solid bars) compared with saline-injected controls (open bars). Aromatase activity in the area basalis (AB) was not affected. b, Experiment 2: treatment with a lower dose of TP (30 µg per day) for 4 days (cross-hatched bars) was more effective than a single 30 µg injection (open bars) in increasing aromatase activity in the POA. It had no effect on either AB or the anterior hypothalamus (AHA): n = 4 in each group. Aromatase activity was measured in homogenates obtained from individual brain samples incubated at 40 °C, pH 7.4 for 15 min with $10 \text{ nM} [1\alpha, 2\alpha(n)^{-3}\text{H}]$ testosterone (specific activity 53 Ci mmol⁻¹, Radiochemical Centre, Amersham) and 1 mg ml⁻¹ NADPH₂ (Sigma, type III). Conversion rates were linear with respect to time and amount of brain tissue used for the incubation⁴. Inset: parasagittal view of the brain showing coronal sections 2, 3 and 4 from which samples AB, POA and AHA (stippled areas) were obtained. See ref. 18 for further details and nomenclature.

periods of treatment were used in experiment 2. In addition to AB and POA the anterior hypothalamus (AHA) was examined. This area is androgen-sensitive, but does not seem to concentrate E_2 to the same extent as the POA. Aromatase activity was higher in the POA after 4 days of treatment than after a single injection (Fig. 1b), although the increase was not as great as that induced by the higher dose (expt 1). Again, this effect seems to be specific to the POA, no change being detectable in AB or AHA. The results of these experiments show that conversion of testosterone to E_2 is stimulated specifically in the POA of castrated male doves by systemic TP treatment. This effect is related to dose and duration of treatment.

In experiment 3, aromatase activity was measured in TPtreated (300 µg per day for 6 successive days) and untreated long-term castrates (n = 4 for each group) using increasing concentrations of the substrate (testosterone) to determine the kinetic properties of the enzyme. Figure 2 shows that the observed increase in activity is probably due to induction of the enzyme: the maximal velocity V_{max} was markedly increased (~fivefold: 250 fmol h⁻¹ per mg tissue as opposed to 48 fmol h⁻¹ per mg tissue) in the POA of castrates after six daily injections. but the Michaelis constant (K_m) was not significantly altered $(2.1 \times 10^{-8} \,\mathrm{M})$ in controls as opposed to $2.7 \times 10^{-8} \,\mathrm{M}$ after TP treatment). Moreover, K_m in the AB was similar in either treated or untreated birds $(2.1 \times 10^{-8} \,\mathrm{M})$ and $2.2 \times 10^{-8} \,\mathrm{M}$, respectively), indicating that the same enzyme is present in both areas, although its tissue concentration is much higher in the POA

These results indicate that the aromatase complex found in the dove brain has a high affinity for its natural substrate, testosterone and that it can be specifically induced in the POA by androgenic stimulation. An earlier study¹⁰ has suggested that

aromatase activity in the rabbit CNS may be influenced by hormonal condition. However, unlike our findings in the dove, aromatase activity was increased nonspecifically both by castration and systemic E₂ administration to intact male rabbits: testosterone had the same effect, but only when administered to intact females. The effect was not localized to a specific area of the brain known to be involved in mediating hormone action on a well-defined biological response, and there was no evidence for induction of the enzyme. Here we have demonstrated a specific induction by androgen on aromatase activity in the POA, a target area known to be associated with oestrogendependent behavioural patterns in the male dove. At this stage, we cannot exclude the possibility that systemically administered testosterone is acting via metabolites formed peripherally or centrally. The enzyme could be induced by E2 itself, because basal rates of aromatization occur in the castrate brain in the absence of androgenic stimulation (Fig. 1). Irrespective of whether testosterone or a metabolite derived from it induces the enzyme, the effect is likely to involve both binding of the active steroid to a specific 'receptor' and genomic activation resulting in de novo synthesis of the aromatase complex.

The active steroid may, however, have an indirect action. Aromatase activity is stimulated in cultured brain cells¹¹ and choriocarcinoma cells¹² by cyclic AMP, and follicle-stimulating hormone (FSH) is a well-known regulator of gonadal aromatase

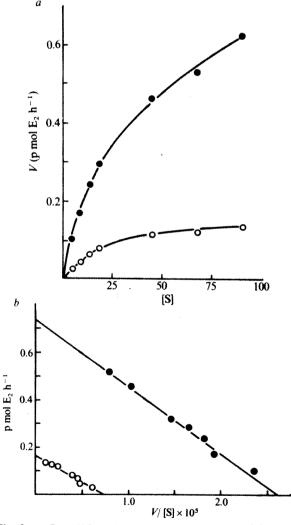

Fig. 2 a, Rate (V) against substrate concentration [S] (nM of testosterone) for aromatase activity in the POA of saline-treated (\bigcirc) or TP-treated (300 µg per day for 6 days, \blacksquare) castrates. b, Eadie–Hofstee plot of the above data, from which the following values were calculated for the apparent kinetic parameters using unweighted linear regression. Saline-treated: $K_{\rm m} = 2.75 \times 10^{-8}$ M, $V_{\rm max} = 250$ fmol h⁻¹ per mg tissue; androgen-stimulated: $K_{\rm m} = 2.04 \times 10^{-8}$ M, $V_{\rm max} = 48$ fmol h⁻¹ per mg tissue.

activity¹³. Moreover, it has been shown recently¹⁴, using Sertoli cell-enriched cultures obtained from immature rats, that some adrenergic neurotransmitter agonists, notably L-isoprenaline and noradrenaline, are as effective as FSH or dibutyryl cyclic AMP in stimulating conversion of testosterone to E_2 (ref. 14). Therefore, testosterone or its active metabolite could act by altering neurotransmitter levels in the POA. Further studies are now being carried out to elucidate the exact mechanism by which systemic TP treatment affects aromatase activity in the dove POA

We suggest that aromatase activity and the production of behaviourally effective oestrogen in the dove POA are modulated by circulating androgens. Because there is evidence for oestrogen-sensitive mechanisms associated with behaviour in the male dove, this finding is likely to be of physiological significance. Thus, oestrogen acting within the brain induces a transition from predominantly aggressive to nest-oriented

courtship interactions with the female¹⁵. Plasma levels of testosterone reach a peak at the stage of the reproductive cycle when the behavioural transition normally occurs¹⁶. Increased aromatase activity in the POA induced by the testosterone peak may therefore mediate this transition. Moreover, oestrogen derived from testosterone in the POA, in addition to its specific effects on nest-orientated courtship, may also play a part in the regulation of testosterone dependent brain mechanisms of behaviour¹⁷. Therefore, the regulatory action exerted by androgen on aromatase activity in the POA is likely to have more than one effect on brain mechanisms involved in the integration of behaviour during courtship in the male dove.

Benzodiazepines reduce stressaugmented increase in rat urine monoamine oxidase inhibitor

Vivette Glover, S. K. Bhattacharya & M. Sandler

Normal human urine inhibits monoamine oxidase (MAO)1. This inhibitory activity, which is also present in rat urine, cannot be accounted for by a large range of known urinary constituents, including certain monoamines or their metabolites, but is caused by an unidentified low-molecular-weight compound(s). Endogenous MAO inhibitors may be important as physiological regulators; there have been reports of a decrease in platelet MAO activity, conceivably deriving from their presence, in a variety of human disease states2. We show here that cold immobilization stress markedly increases the output of rat urine MAO inhibitor, and that this increase is attenuated by benzodiazepine drugs.

Figure 1 shows that control urine samples from unstressed rats produced comparatively little MAO inhibition. Cold immobilization stress increased fivefold the degree of MAO inhibition induced by rat urine, with no concomitant effects on urinary pH or creatinine concentration. Pretreatment of rats with lorazepam [0.25 and 1.25 mg per kg intraperitoneally (i.p.)] gave rise to a statistically significant decrease in the concentration of stress-induced urinary MAO inhibitor. The output of inhibitor at a dosage of 1.25 mg per kg lorazepam was less than that at 0.25 mg per kg. Similarly, acute doses of chlordiazepoxide (5, 10 and 50 mg per kg) also significantly reduced the output which was less at higher dosage.

Acute administration of benzodiazepines causes sedation whereas, after chronic administration, tolerance develops. Output of inhibitor was also examined, therefore, after 5 days' administration of 10 and 50 mg per kg chlordiazepoxide and found to remain significantly less than that of the stressed group

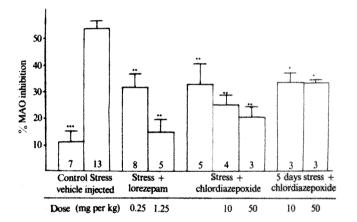

Fig. 1 Effect of cold stress in rats, with and without various benzodiazepine dosage schedules, compared with control animals. Values are means \pm s.e. No. of animals is given at the base of each bar. *** P < 0.001 compared with vehicle-injected stressed group (2-tailed Student's t-test). ** P < 0.01, different from vehicleinjected stressed group (Neuman-Keul's test). * P < 0.05, different from vehicle-injected stressed group (Neuman-Keul's test). The data from the stressed group were subjected to analysis of variance and showed a significant drug effect (F = 8.76, d.f. = 7.35); P <0.0001. The test system consisted of 100 µl phosphate buffer (100 mM, pH 7.4), 20 µl of urine, 20 µl MAO preparation and ¹⁴C-tyramine, final concentration 83 μM (for assay system, see ref. 1). All assays were carried out blind and in duplicate. Male hooded rats (Olac UK) (250-350 g) were starved overnight but allowed water. Controls were subjected to minimal handling and allowed to move freely in their cages. Stress was induced by placing rats in a restraint cage for 2 h at 4°C. Rats were decapitated with a guillotine and urine removed from the bladder by direct puncture. The urine was frozen and stored at -20 °C before assay. Drugs were given by i.p. injection immediately before restraint. Chlordiazepoxide hydrochloride (Roche) was dissolved in distilled water to various concentrations to give an injection volume of 2 ml per kg. Lorazepam (John Wyeth) was dissolved in a vehicle of 2% benzyl alcohol, 18% polyethylene glycol and 80% propylene glycol in a concentration of 4 mg ml⁻¹. It was then diluted with distilled water to give injection volumes of 2 ml per kg. Stressed but drug-free animals received equivalent vehicle or water injections. For the chronic experiments, injections were given once per day for 5 days.

Table 1 Effect of stress and benzodiazepines on pH, creatinine levels and total bladder urine

	pН	Creatinine (mmol I ⁻¹)	Total bladder urine (mg)
Unstressed control (7)	6.6 ± 0.1	4.6 ± 1.2	199 ± 30
Stressed: Vehicle-injected (13) Lorazepam (0.25 mg per kg) (8) Lorazepam	6.5 ± 0.1 6.4 ± 0.1 6.6 ± 0.2	3.4 ± 0.5 2.5 ± 0.4 3.4 ± 1.0	154 ± 30 107 ± 10 169 ± 44
(1.25 mg per kg) (5) Chlordiazepoxide (5 mg per kg) (5)	6.6 ± 0.2	2.1 ± 0.7	103 ± 13
Chlordiazepoxide (10 mg per kg) (8)	6.5 ± 0.2	2.5 ± 0.8	125 ± 18
Chlordiazepoxide (50 mg per kg) (3)	6.4 ± 0.2	2.5 ± 0.7	131 ± 31
Chlordiazepoxide (10 mg per kg× 5 days) (3)	6.8 ± 0.2	4.9 ± 0.8	159±18
Chlordiazepoxide (50 mg per kg× 5 days) (3)	6.6 ± 0.2	4.8 ± 0.6	164 ± 35

Numbers in parentheses indicate number of urine samples pooled.

(Fig. 1). Given acutely, chlordiazepoxide at 10 and 50 mg per kg caused sedation to 58% and 6% of control levels on an activity scale, whereas after 5 days the levels were 89% and 51% respectively3. These effects do not seem to correlate with inhibitor output, which remained significantly reduced after 5 days of 10 mg per kg chlordiazepoxide, suggesting that the benzodiazepine effect was not due solely to sedation.

Inhibitory potency was measured in a standard volume of urine. However, there was no significant difference in urinary pH, urine mass or creatinine concentration between the stressed and control groups, nor between stressed and drug-treated groups (Table 1). There was no correlation between any of these values and output of urinary MAO inhibitor. It therefore seems most unlikely that a difference in urinary flow could account for these findings.

Ethyl acetate extracts of acidified pooled urine samples produced results similar to those produced by unextracted urine; the stressed group exhibited more inhibition than control, with intermediate values in benzodiazepine-treated groups, but with an approximate doubling of percentage inhibition in each (Table 2). This extraction behaviour points to a compound(s) of acidic or neutral nature and indicates that it is not a monoamine. The inhibitor is not generated spontaneously; activity remains constant when fresh rat urine is left at room temperature for 24 h.

Table 2 MAO inhibition by ethyl acetate extracts

	% Inhibi	tion of MAO
	Pooled	Ethyl acetate
	urine	extract
Unstressed control (7)	17.4	47.1
Stress vehicle-injected (13)	48.2	72.4
Lorazepam (13)	29.9	63.4
Chlordiazepoxide (12)	33.9	62.3

Numbers in parentheses denote number of urine samples pooled. Controls for this experiment consisted of four Wistar and three hooded rats. Equal volumes of urine from each rat in the stress and acute drug-treated groups in Table 1 were pooled. The urinary inhibitor was extracted into ethyl acetate as follows: pooled urine samples were diluted 1 in 10 with saturated NaCl acidified to pH 0.9 with HCl. This was shaken with an equal volume of ethyl acetate and centrifuged to separate the layers. The upper layer was aspirated off, the ethyl acetate removed by passing nitrogen through it and the remaining solids taken up to the original urinary volume with 100 mM phosphate buffer, pH 7.4. Blanks, in which water replaced urine, gave no MAO inhibition.

	Table 3 MAO inhibition by carbolines						
Drug	Structure		% MAO inhibition				
		10^{-3}	10^{-4}	10^{-5}	10^{-6}M		
Ethyl β-carbo (FG 7098)	line-3-carboxylate	27.3	13.7	6.0	0.7		
	CO ₂ C ₂ H ₄						
2,9-Dimethyl carboline	1,2,3,4-tetrahydro-β	66.8	54.0	35.4	14.3		
	NCH,						
1,2,3,4-Tetrah	ydro-β-carboline	45.6	21.1	7.8	0		
	NH NH						
Ethyl 3,4-dihy 3-carboxylate	dro-1-methyl-β-carboline-	29.4	14.2	0	0		
	СО ₂ С ₂ Н,						
3,4-Dihydro-B	d-carboline-3-carboxylic acid	32.4	26.5	24.3	0.8		
	Соон						

The drugs were dissolved in distilled water and the pH adjusted to 7.0. 100 µl of each concentration was used in the reaction mixture instead of

The differing patterns of output between the groups investigated seems unlikely to reflect any variation in dietary intake. for all urine samples were obtained after an 18-22-h fast. Nor is it likely to mirror any differences in gut flora; we have found previously that the excretion of urinary inhibitor is similar in control and germ-free rats1.

It is possible that this urinary inhibitor derives from catecholamines or corticosteroids, the output of both of which is increased in this type of stress⁴. However, we have previously shown that none of the catecholamines or their major metabolites is present in human urine in sufficient concentration to account for its MAO inhibitory properties¹. In addition, there is no evidence that corticosteroids or their derivatives can inhibit MAO. We have, therefore, speculated about its possible identity in terms of a third chemical system involved in stress, possibly related to the β -carboline group of compounds⁵. Barker et al. have recently detected three tetrahydro- β -carbolines as normal constituents of rat brain and have also found particularly high concentrations in the adrenal gland. The molecular weight of the urinary inhibitor is of the appropriate order of 200 and carbolines such as harmine and harmaline are very potent MAO inhibitors⁷. Braestrup et al.⁸ have extracted a β-carboline from human urine which is a high-affinity ligand for benzodiazepine receptors. We have, therefore, tested Braestrup's compound (FG 7098) and four other structurally related compounds and found that they inhibit MAO in our test system only at concentrations much higher than the 10^{-8} M range in which FG 7098 was found in human urine (Table 3). However, Braestrup et al. indicate that the ester group of their compound was probably an artefact of the extraction procedure. As slight alterations in structure may markedly affect pharmacological properties, it remains possible that the MAO inhibitor or inhibitors we are studying are related to this compound or are endogenous compounds with a similar range of pharmacological actions.

Modulation of affinity of postsynaptic serotonin receptors by antidepressant drugs

G. Fillion & M. P. Fillion

Laboratory of Pharmacology, Pasteur Institute, F75724 Paris Cédex 15, France

Antidepressant drugs are generally thought to act by changing aminergic neurotransmission. Thus, according to indoleamine hypothesis1, antidepressant drugs increase the amount of serotonin (5-HT) available at the receptor level by inhibition either of 5-HT uptake or of its degradative enzyme (monoamine oxidase)2. Various experimental observations have, however, suggested that the effects of antidepressant drugs may be located at the postsynaptic receptor level³⁻⁷. We report here that antidepressant drugs alter the structural conformation of the postsynaptic serotoninergic receptor in synaptosomal membranes isolated from rat and horse brains in such a way as to inactivate them.

Serotonin postsynaptic receptors are regulated by a mechanism involving several conformational states of the recognition site for 5-HT⁸, with different affinities for 5-HT. The transition of the receptor protein from one state to another modulates the activity of the effector system, a 5-HT-sensitive adenylate cyclase^{9,10}. In the resting state, the recognition site binds 5-HT with a low affinity. Exposure to an agonist (but not to an antagonist) induces the structural transition of the receptor to an intermediate state stabilized by GTP; this state corresponds to the activation of the adenylate cyclase. The transition process ends with a final high-affinity state which can no longer activate the effector (desensitized state).

Our data consist of measurements of the affinity of ³H-5-HT for synaptic membranes pre-treated with various drugs (Fig. 1). Pre-exposure of the membranes to imipramine (10 nM) changed the affinity of the receptor for 5-HT; the affinity constant, $K_{\rm D}$, was ~12 nM in the control and ~2 nM after pre-exposure to the antidepressant (Fig. 1). This effect is comparable with that observed after pre-exposure of the membranes to 5-HT itself (Fig. 1). Imipramine is also effective at a lower concentration (1 nM) where a similar increase in affinity is observed (Fig. 2a) and in this case, the total number of binding sites is almost unchanged (<15%). The drug also produced an increase in affinity at a higher concentration (0.1 µM), but there was a marked reduction in the number of sites binding ³H-5-HT (40-60%). Note that this effect is not the result of a direct binding of the imipramine to the serotoninergic site as the $K_{\rm I}$ (10 μ M) of the drug (measured using imipramine concentrations which competitively inhibit ³H-5-HT binding) is several orders of magnitude greater than those which produce an increase in affinity. Furthermore, the presence of a competitive inhibitor would be expected to decrease the apparent affinity, not increase it as seen here.

The affinity change induced by imipramine is not observed in the presence of GTP (10^{-4} M, Fig. 2b). Other tricyclic antidepressant drugs have also been tested with similar results (see Table 1). Other non-antidepressant substances tested, chlorpromazine (10 nM and 10 µM, Fig. 2b), antiserotonins, cinan-

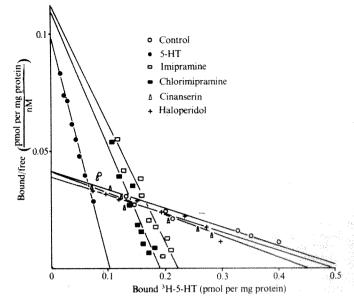

Fig. 1 Scatchard plot of ³H-5-HT binding to synaptic membranes preexposed to various drugs. Assays were done using membranes isolated from rat brains. Sprague-Dawley rats were decapitated and their brains isolated on ice and the whole forebrain dissected. These tissues were homogenized and treated as described elsewhere¹² to obtain enriched preparations of synaptosomal membranes by differential and density gradient centrifugation. Synaptosomal membranes were preincubated at 37 °C for 10 min to eliminate the endogenous 5-HT which could still be present and which could interfere with the binding of ³H-5-HT as shown previously ^{18,19}. These were then diluted 10 times in Tris-HCl buffer, 50 µM, pH 7.4, containing nialamide (100 μM) and ascorbic acid (0.1%). The membranes were then pre-exposed to 5-HT (10 nM) at 37 °C for 10 min or 15 min or to the substance being investigated at the indicated concentration (generally 10 nM); controls were incubated in buffer. The samples were washed either by centrifugation (20,000g, 10 min) and dilution in the initial volume of buffer, or by simple dilution (20-fold). Aliquots of these washed membranes were incubated at 22 °C for 8 min in the presence of various concentrations of ³H-5-HT (2-30 nM). Specific binding was determined as previously described using a rapid filtration technique. Results for membranes isolated from striatum or hippocampus of horse brain were not significantly different. In the experiment shown, rat brain membranes isolated from striatum were pre-exposed to buffer or 10 nM of the indicated drug and washed. After incubation in the presence of ${}^{3}H-5-HT$, the K_{D} observed after preincubation in buffer, 5-HT, imipramine, chlorimipramine, cinanserin and haloperidol was 12.4, 1.07, 2.08, 1.56, 12.7 and 13.5 nM, respectively

serin, methysergide, methergoline, methiothepin (10 nM), neuroleptics, haloperidol (10 nM) and fluphenazine (10 nM) had no effect.

Interestingly, the change in affinity induced by 5-HT is inhibited by methysergide (10 µM) added together with the amine during pre-exposure of the membranes; a similar inhibition of the effect of imipramine is observed in the same experimental conditions.

The change in the affinity for ³H-5-HT induced by preexposure of the membranes to 5-HT itself occurs in rat brain synaptosomal preparations and in membranes isolated from striatum8 or from hippocampus. This phenomenon seems to be widespread for serotoninergic sites as we also observed it in membranes isolated from horse brain (striatum and hippocampus). As we have previously shown¹¹, these sites are located on postsynaptic membranes. The affinity constant observed for 5-HT binding to membranes which had not been pre-exposed is ~15 nM, whereas membranes pre-exposed to 5-HT and washed bind 5-HT with a higher affinity $(K_D = 1.8 \pm 0.4 \text{ nM})$. This increase in affinity is induced by serotoninergic agonists and not by antagonists. As previously reported^{9,10}, these affinity changes might correspond to structural changes of the receptor protein as they do not occur after pretreatment of the membranes with a sulphydryl group reagent.

In experimental conditions which produce a high-affinity binding for 5-HT, no adenylate cyclase activation is observed, whereas in the presence of GTP (or GppNHp) the low-affinity binding is stabilized and adenylate cyclase activation occurs^{9,10}. These observations and other information on binding kinetics

Fluphenazine

Haloperidol

Table 1 Affinity constant of ³ H-5-	HT binding to synaptic membranes			
Pre-exposure	$K_{\mathbf{D}}$ (nM)			
None	15.3 ± 1.26 (14)

Chlorpromazine	14.24 ± 1.95 (5)			

Affinity changes of 3 H-5-HT binding induced by various drugs. Membranes were pre-exposed to the drug being investigated (10 nM) at 37 °C for 10 min, diluted 20-fold in Tris-HCl buffer (50 mM, pH 7.4) and incubated at 22 °C for 8 min, in the presence of various concentrations of 3 H-5-HT. The radioactivity specifically bound was determined by a rapid filtration technique. The affinity constants are the means \pm s.e. of 3-6 assays. For the drugs tested twice only, the values observed for individual assays did not differ by >30% of the mean.

 10.7 ± 1.9 (3)

led us to propose the regulatory mechanism summarized above.

All the drugs tested which have clinical properties of antidepressants, except the group of the inhibitors of monoamine oxidase (IMAO), are able to increase the affinity of the 5-HT receptor for the amine itself. Active drugs include tricyclic antidepressants (imipramine, chlorimipramine, amytriptyline, trimeprimine, desipramine) which are also inhibitors of 5-HT or noradrenaline (NA) uptake, other antidepressants which are only weak inhibitors of amine uptake (iprindol or mianserin) and doxepin which is considered to be a weak antidepressant. The changes in affinity induced by these drugs do not therefore seem to be related to their capacity to inhibit the uptake of 5-HT or NA. Furthermore, many of the drugs, are used at concentrations which have no effect on the monoamine uptake¹². The clinical properties of fluoxetine and fenfluramine as antidepressants have not been established.

Note that the antidepressants of the IMAO group are ineffective. They are known to act on the degradative enzyme of 5-HT, resulting in an increase in the availability of 5-HT in the synaptic cleft. These drugs do not increase the affinity of the binding site for ³H-5-HT. The assay could be performed in the presence or absence of 100 μ M nialamide without any alteration to the ability of the binding site to be either in a conformational state corresponding to a high or a low affinity for ³H-5-HT.

Chlorpromazine, which is not considered to possess true antidepressant properties although it has a chemical structure very like that of imipramine, is unable to increase the affinity of the 5-HT receptor for its ligand even at concentrations up to 10^{-6} M; haloperidol and fluphenazine, neuroleptic drugs which lack antidepressant properties, are also ineffective.

Thus, this effect of the antidepressant drugs on the post-synaptic serotoninergic receptor seems to be specific. It does not occur directly at the serotoninergic site by competition with 5-HT as the affinity constants of these drugs for the 5-HT site correspond generally to a rather low affinity in the range $1-10\,\mu\text{M}^{13}$. Several hypotheses might be proposed to explain this effect. The antidepressant drugs might act by binding to a specific site corresponding to the existence of an endogenous imipramine-like ligand. In that case, the occupation of the site would modulate the conformation of the serotoninergic recep-

tors possibly through an allosteric process. Binding sites for ³H-imipramine have already been described in synaptosomal membranes from rat brain¹⁴. On the other hand, these drugs might act by changing some physical characteristics of the membranes in a manner analogous to that described by Hirata and Axelrod¹⁵ in the close vicinity of the serotoninergic receptor.

The drugs which induce the transition of the site to high affinity are either 5-HT agonists or antidepressants. We have shown that the binding of 5-HT to this conformation of the site is unable to activate the adenylate cyclase and therefore produces a desensitized state of the receptors; antidepressant drugs thus

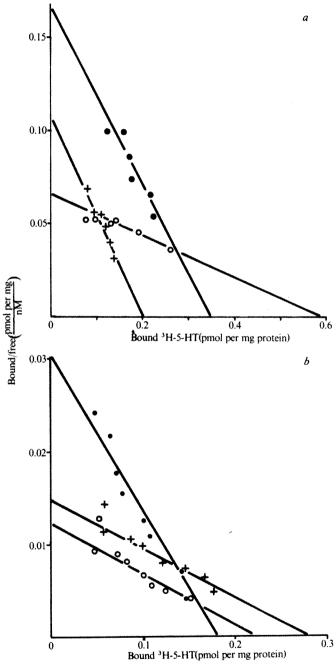

Fig. 2 a, Effect of the pre-exposure of membranes to imipramine on the binding of ${}^{3}\text{H-5-HT}$ to its specific sites. Scatchard plot of the binding curves for membranes not pre-exposed to imipramine (control, \bigcirc); and pre-exposed to 1 nM (+) and 10 nM (\bigcirc) imipramine. Experimental conditions were the same as for Fig. 1. The affinity constants for ${}^{3}\text{H-5-HT}$ were 11, 2.2 and 2.04 nM for control, 1 and 10 nM imipramine, respectively. b, Lack of effect of imipramine pre-exposure on purified synaptosome membranes treated with GTP. The same experimental conditions were used as for Fig. 1 except that the test membrane preparation contained GTP during pre-exposure to imipramine. The corresponding affinity constants were: $K_D = 5$, 19.1 and 17.2 nM after pre-exposure of the membranes to buffer (control, \bigcirc), imipramine (10 nM, \bigcirc) and imipramine + GTP (10 μ M, +), respectively.

seem to inactivate the postsynaptic 5-HT receptor. Because drugs which lack antidepressant properties do not have this capacity, we suggest that the clinical properties of tricyclic antidepressants are related to their capacity to desensitize the postsynaptic 5-HT receptor.

The structural changes induced by tricyclic antidepressants might represent a critical step in the receptor modifications observed after long-term administration^{7,16,17}. Our results support new concepts of the mechanism of action of antidepressants and indicate that the clinical properties of these drugs might involve an effect on the postsynaptic 5-HT receptor.

Transplanted adrenal chromaffin cells in rat brain reduce lesion-induced rotational behaviour

William J. Freed, John M. Morihisa, Eleanor Spoor, Barry J. Hoffer*, Lars Olson†, Ake Seiger† & Richard Jed Wyatt

Rats with unilateral lesions of substantia nigra pars compacta (SN), the area of the brain containing most dopamine-containing neurones, are a widely recognized animal model of Parkinson's disease¹⁻⁴. When given dopamine agonists such as apomorphine, such rats rotate in a direction contralateral to the lesion, presumably because of the development of supersensitive dopamine receptors in the striatum ipsilateral to the lesion. When grafts of embryonic SN are placed in the lateral ventricle^{5,6}, or into a transplant cavity⁷ adjacent to the striatum in animals with SN lesions, this rotational behaviour has been shown to decrease. Histochemical examinations have shown that axons from the grafts have grown into the striatum⁵⁻⁷, and biochemical measurements indicate that dopamine concentrations are increased in areas of the striatum adjacent to the SN grafts6. Nevertheless, an obvious problem with this technique, both for basic research and possible clinical applications, is the requirement for fetal central nervous donor tissue. We now describe how grafts of adrenal medulla can be used with similar effects, involving chromaffin cells.

There are several reasons for considering the adrenal medulla as a potential replacement for fetal SN grafts. First, the normal

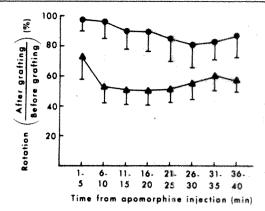

Fig. 1 Contralateral apomorphine-induced turning after grafting. expressed as a percentage of turning before grafting, is shown as a function of time after apomorphine injections. To derive these data, the 40-min testing sessions were divided into eight 5-min segments. For each of these segments, a mean pregrafting rotation rate was determined, and the rotation rate after grafting was expressed as a percentage of this pregrafting rotation rate. Triangles indicate animals that received adrenal medulla grafts (n = 13); circles indicate control animals that received sciatic nerve grafts (n = 15). Vertical lines indicate s.e.m. A two-way analysis of variance for one repeated measure showed a significant main effect of treatment (adrenal versus sciatic nerve grafts [F(91,26) = 4.40]; P = 0.043]. The main effect of measures and measures × treatment interactions were not significant (F(7.182) = 1.71; P = 0.109) and (F(7,182) = 0.81; P = 0.417, respectively].

adrenal medulla produces dopamine as an intermediary in the synthesis of adrenaline^{8,9}. Second, adrenal chromaffin cells, which are normally rounded in shape, become angular and develop processes when grown as grafts in the anterior eye chamber¹⁰⁻¹² or when grown in culture in the absence of corticosteriods¹³⁻¹⁵. Finally, processes originating from intraocular adrenal medulla grafts can innervate intraocular grafts of cerebral cortex, as demonstrated by histochemical studies14

Unilateral SN lesions were produced^{5,6} in male Sprague-Dawley rats by stereotaxic injections of 6-hydroxydopamine hydrobromide into the right SN. Approximately 2 months later, the animals were tested for apomorphine-induced (0.1 and 0.25 mg per kg subcutaneously) rotational behaviour using an automated apparatus. The smaller of the two doses that produced at least 80 counterclockwise rotations in 40 min was used for each animal. Animals turning at less than this rate were not used. After the initial screening, rotational behaviour was re-examined for five to seven additional sessions to obtain a stable baseline for each rat.

Adrenal glands were removed from young adult Sprague-Dawley rats (125-200 g) and the medulla dissected free. The dissected medulla was then bathed in sterile lactated Ringers at room temperature. A cut was made in the surface of the medulla to enable it to be opened, and the interior was removed. This method was used to avoid inclusion of the adrenal cortex in the graft. Four to six grafts were implanted in the lateral ventricle on the 6-hydroxydopamine-lesioned side in each of 13 rats (age at least 5 months) using Pellegrino and Cushman¹⁷ coordinates of 1.5 mm lateral and 1.5 anterior to bregma, 3.5-4.0 mm below the dura, as previously described. Control (n = 15) animals received grafts of sciatic nerve instead of adrenal medulla.

Adrenal medulla (n = 13) or sciatic nerve (control) grafts (n = 15) were implanted and 2 months allowed for survival and growth of the graft tissue. At this time, rotational behaviour was examined for five 40-min sessions, and some of the animals killed for histochemical studies.

When the rats were tested 2 months after transplantation, rotational behaviour was significantly less in the animals with adrenal medulla grafts than in those with sciatic nerve grafts (Fig. 1). Histochemical fluorescence studies of six randomly selected rats showed the denervations of the caudate nucleus to

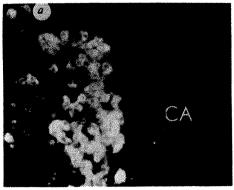

Fig. 2 Falck-Hillarp fluorescence microscopy of intraventricular adrenal medulary grafts. a, Overview of cluster of strongly fluorescent chromaffin cells within a graft. Some cells are elongated or polygonal with short coarse processes (upper left), but very few thin nerve fibre-like processes have formed (CA, caudate). ×160. b, Close-up of two chromaffin cell clusters. Three nuclei are seen in the lower cluster: one cell has a tapering nerve fibre-like process (arrow). ×290.

be essentially complete, with only a few fine terminals remaining in one rat. Grafts with catecholamine-containing chromaffin cells were found in five of the six animals. As shown in Fig. 2, these cells had developed polygonal shapes and were usually grouped in one or more small clusters within the grafts. Two types of fluorescent cells were found in the adrenal grafts, similar to the noradrenaline (very strongly fluorescent) and adrenaline (moderately fluorescent) cells present in normal adrenal medulla^{21,22}. Some of these cells had fine elongated processes, but very few fibres were seen to leave the grafts and enter the host brains. The total numbers of chromaffin cells found in the grafts counted by methods previously described⁵, were 880, 4,080, 66, 517 and 2,134, respectively, for the five animals. Adrenal cortex was also found in the graft that contained 4,080 chromaffin cells. Rotational behaviour was not reduced in this animal, nor in the animal that had only 66 chromaffin cells.

The observations suggest that adrenal medulla grafts can reduce lesion-induced rotational behaviour, even though there was no clear evidence that the grafts actually reinnervated the host caudate nucleus. Although the transplanted chromaffin cells were elongated and produced fine fibres, these fibres were found almost entirely within the grafts, and rarely penetrated into the caudate nucleus. This suggests that catecholamines or other substances diffused from the grafts to receptor sites in the caudate nucleus in sufficient quantity to reduce caudate dopaminergic supersensitivity and consequently, apomorphineinduced rotation.

Adult adrenal medullary cells show a remarkable phenotypic plasticity in response to environmental changes. Thus, when pieces of adrenal medulla are grafted into the anterior chamber of the eye, chromaffin cells will migrate into the sympathetically denervated host iris and form catecholamine-containing nerve fibres that reinnervate the iris10. Tissue culture experiments show that chromaffin cells of rodents and man express the endocrine phenotype in the presence of glucocorticoids and the sympathetic adrenergic neurone phenotype in the absence of glucocorticoids and the presence of nerve growth factor (NGF)^{12-15,23}. Thus, histochemical changes in grafted adrenal medullary tissue in the eye may be explained by the removal of the normal adrenal cortical environment and increased amounts of NGF in the sympathetically denervated host iris (see ref. 24). We have recently shown that chromaffin cells grafted into the eye chamber can also innervate adjacent grafts of brain tissue16. In this case, fine varicose fibres, typical of telencephalic adrenergic afferents, were found. In contrast to rat chromaffin cells, bovine chromaffin cells show little or no evidence of fibre

production when cultured or transplanted to the anterior eye chamber or brain 15,25

Although the results reported here clearly demonstrate longterm survival of grafted chromaffin cells and reduction of apomorphine-induced rotational behaviour, there was only partial transformation of chromaffin cells towards the neuronal phenotype. Brain tissue does not seem to contain or produce any appreciable amount of NGF^{26,27}. Therefore, these results agree well with the findings from tissue culture that chromaffin cells will survive and produce small numbers of nerve fibres without NGF, but require NGF for extensive fibre formation (see refs. 15,23). Because of the sparsity of innervation of host caudate, the present behavioural results are probably best explained by a release of catecholamines from the grafts and subsequent diffusion of the amines to supersensitive dopamine receptors. Fluorescence microscopy demonstrated that both noradrenaline and adrenaline cells were present in at least some of the grafts. although the proportion of noradrenaline cells seemed higher in grafts than in normal adrenal medulla. The relative role of dopamine, noradrenaline and adrenaline and other possible neurotransmitters or peptides released by the grafts, such as enkephalin²⁸⁻³⁰, remains to be determined. Experiments are in progress to measure the concentrations of various catecholamines in the graft and adjacent host brain. Conceivably, release might also be influenced by any fibres from the host brain which innervate the grafted tissue, analogous to the normal regulation of medullary catecholamine release by cholinergic afferent input. A further question would be the presence of all-or-none action potentials and impulse-dependent transmitter release. Action potentials have been reported in the NGF-transformed phaeochromocytoma line PC-12 Greene³¹

Although many questions remain unanswered, the data reported here suggest that it may be possible to use adrenal medulla in place of fetal SN as a source of tissue for catecholamine-containing grafts. If further studies are successful, peripheral autografts could be potential replacements for destroyed or damaged central neurones. We are now atempting to produce adrenal autografts in subhuman primates and to develop protocols to increase fibre ingrowth from adrenal grafts to the caudate nucleus.

Immunological enhancement of tumour allografts following treatment of mice with TNP-conjugated alloantigen and anti-TNP antibody

L. V. Hutchinson & L. Brent

Department of Immunology, St Mary's Hospital Medical School, London W2 1PG, UK

Immunological enhancement—the prolonged survival of tumour or organ allografts brought about by passive immunization of the host with alloantibody directed against the graft's antigens—has not yet been applied successfully to clinical organ transplantation. There are many reasons for this, among them the difficulty of preparing the required battery of alloantisers and the danger of causing hyperacute rejection of kidney allografts. We show here that it should be possible to circumvent both these problems by using a xenogeneic antibody directed against a well defined hapten rather than against histocompatibility antigens.

The mechanism of immunological enhancement is still a matter for debate¹⁻⁵. One hypothesis advanced to account for antibody-mediated suppression of specific immune responses is that graft antigen and anti-graft antibody combine to form complexes which are bound specifically by the antigen receptors of lymphocytes, by virtue of free antigenic determinants. In this way, antigen-specific cells (ARCs) of the recipient are coated with antibody indirectly bound to the lymphocyte membrane through an antigen bridge. It is postulated that these opsonized ARCs are subsequently destroyed by Fc-receptor-bearing host cells such as macrophages⁶⁻⁹. The most direct evidence for the hypothesis of ARC opsonization (ARCO) (reviewed in ref. 4) comes from experiments in which syngeneic radiolabelled ARCs were taken up by the reticuloendothelial system when injected intravenously (i.v.) into rats bearing enhanced kidney transplants^{6,7} or mice bearing enhanced skin allografts¹⁰. This is strongly supported by experiments in which mice were pretreated with complexes between sheep red blood cells (SRBCs) and anti-SRBC antibodys or with allogeneic cells and alloantibody9.

Following the ARCO hypothesis, one possible prediction is that the antigenic determinant in the complex bound by receptors of ARCs need not be identical with that reacting with the

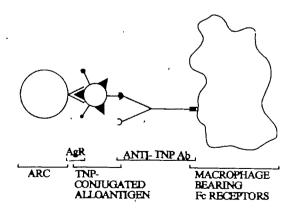

Fig. 1 The concept of opsonization of alloreactive ARCs by TNP-conjugated alloantigen and anti-TNP antibody. Free alloantigens determinants (A), in complexes formed between TNP-conjugated alloantigens (where ♥ signifies TNP determinant) and anti-TNP antibody, are specifically bound by the antigen receptor (AgR) on the antigen-reactive cells (ARCs) In this way ARCs are opsonized by antibody indirectly bound to the cell surface through an antigen bridge, to be destroyed by Fc -receptor-bearing host cells.

enhancing antibody (Fig. 1). It has indeed been shown that, to achieve the most efficient opsonization of ARCs, the ARC receptors and the antibody should kind to different determinants in the complex9, thus avoiding blocking of the determinants required for the linkage to cell receptors. Sinclair and Law11 have recently shown that complexes formed between trinitrophenyl (TNP)-conjugated alloantigen and anti-TNP antibody can suppress in vitro alloimmune responses, and that anti-TNP antibody enchances the in vivo growth of TNPconjugated allogeneic tumour cells. We too have found that alloantigens coupled to TNP retain alloantigenic activity, that they can be specifically bound by alloreactive ARCs, and that ARCs which have bound TNP-alloantigen/anti-TNP antibody complexes are specifically diverted to the liver when injected i.v. into normal mice12. Our present experiments confirm that anti-TNP antibody enhances TNP-conjugated tumour allografts and we have extended these observations by showing that complexes between TNP-conjugated alloantigen and anti-TNP alloantibody specifically enhance the growth of unmodified tumour cells.

The mice used were from inbred strains BALB/c (H-2^d). DBA/2 (H-2 $^{\circ}$), C57BL/6 (H-2 $^{\circ}$) and A/J (H-2 $^{\circ}$) bred by the Animal Department of St Mary's Hospital Medical School, London. They were 6-10 weeks old at the start of each experiment. Anti-H-2^d and anti-H-2^b allogntisers were raised by injecting five doses of 2×10^7 allogeneic (BALB/c or C57BL/6) spleen cells intraperitoneally (i.p.) into female A strain mice at 2-week intervals. Anti-TNP serum was produced in female New Zealand White rabbits by the injection of 500 µg TNP-KLH (keyhole limpet haemocyanin) antigen in complete Freund's adjuvant on days 0 and 21, followed by i.v. booster inoculi of 1 mg of the same antigen in saline on days 45 and 59. The rabbits were bled on day 70 and the freshly prepared sera were stored at -20 °C. P815 mastocytoma and EL-← leukaemia cells were maintained by i.p. passage in DBA/2 and C57BL/6 mice, respectively. Conjugation of cells with TNP¹³ was achieved by incubating splenic lymphocytes or tumour cells at a concentration of 2.5×10⁴ per ml in 10 mM trinitrobenzene sulphonic acid (TNBS, Sigma) dissolved in phosphate-buffered saline (PBS), pH 7.2, at 37 °C for 10 min. The cells had been washed in PBS before incubation and were washed four times after incubation. The cell membrane antigen was prepared by a modification of the technique described by Standring and

Table 2 Enhancement of P815 tumour cells by TNP-BALB/c antigen and anti-TNP serum

10 ⁴	0.01	51.6 ± 7.0	NS

MTA, mean tumour area estimated on day 7. Values are for groups of five mice NS, not significant.

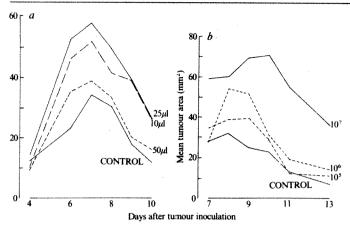

Fig. 2 a, Enhancement of TNP-conjugated tumour by anti-TNP serum. P815 mastocytoma cells (H-2^d) were hapten-conjugated by incubation in 10 mM TNBS (see text). 10⁷ viable TNP-P815 cells were injected s.c. into A strain (H-2^a) mice and 0-50 μl rabbit anti-TNP-KLH serum was injected i.p. Control mice received no serum. Tumour size was measured at intervals after inoculation and the mean tumour area (MTA) calculated as described in the text. b, Enhancement of tumour allografts by TNP-conjugated alloantigen and anti-TNP serum. 10⁷ viable P815 mastocytoma cells (H-2^d) were injected s.c. into A strain (H-2^a) mice. TNP-conjugated BALB/c (H-2^d) cell membrane antigen (see text), derived from 10⁵-10⁷ cells, was injected i.v. and 0.1 ml rabbit anti-TNP-KLH serum was given i.p., both at the time of tumour inoculation. Control mice received no treatment. Tumour size was measured on days 7-13 and the MTA calculated.

Williams 14 . Thus, TNP-conjugated or unmodified spleen cells were pelleted, resuspended in 2% Tween 40 (Sigma) in 0.1 M Tris-HCl buffered saline (pH 8.0) and stirred at 0 °C for 60 min. The cells were then homogenized by 20 strokes of a Dounce glass homogenizer and the suspension was centrifuged at 2,000g for 15 min. The supernatant was centrifuged again, this time at 100,000g for 45 min, and the sedimented membrane material was resuspended in PBS and stored in aliquots at -80 °C.

The experimental design was as follows. 10^7 tumour cells in 0.1 ml balanced salt solution (BSS) containing 10% fetal calf serum (FCS) were injected subcutaneously (s.c.) into A strain mice on day 0. Different doses of antigen $(0-10^8$ cell equivalents) and alloantiserum or anti-TNP serum (0-0.5 ml) were injected i.v. and i.p., respectively, within 1 h of tumour cell inoculation. The resulting tumours were measured from day 6 onwards. The diameter (d) of the tumours was measured in two planes at right angles to each other and the tumour surface area (A) was calculated according to the formula: $A = \pi(d_1 \times d_2)/4$. The statistical significance of the data was assessed using Student's t-test.

A-anti-BALB/c (anti-H- 2^d) serum enhanced the growth of the P815 (H- 2^d) tumour in A strain (H- 2^a) mice (Table 1a). The optimal effect was obtained using 25 μ l per mouse; presumably, higher doses were cytotoxic to the grafted cells (see below). Similar results were obtained using the EL-4 (H- 2^b) tumour cells and an anti-C57BL/6 (H- 2^b) serum (Table 1b). The enhanced growth was clearly strain specific in that A-anti-BALB/c serum did not enhance the growth of EL-4 and anti-C57BL/6 serum did not enhance the growth of the P815 tumour (results not shown).

Similarly, TNP-antiserum enhanced the growth of TNP-conjugated tumour cells (TNP-P815; Fig. 2a), thus confirming the work of Sinclair and Law¹¹. Again, 25 μ l proved to be optimal although 10 μ l were here almost as effective; 50 μ l had no

significant effect. TNP-P815 cells are, in fact, readily lysed in vitro by anti-TNP serum and complement (I.V.H., unpublished), a finding that almost certainly accounts for the lack of success with the higher dose.

Figure 2b shows that unmodified P815 tumour implants were enhanced through the use of TNP-BALB/c membrane antigen and anti-TNP antibody. Strain A mice were given 10⁷ unmodified tumour cells s.c., 0.1 ml anti-TNP serum i.p., and TNP-modified cell membrane antigen at 10^5-10^7 cell equivalents per mouse i.v. Tumour growth was considerably enhanced in animals treated with TNP-conjugated membranes obtained from 10⁷ cells and with 0.1 ml antiserum, whereas doses representing 105 or 106 cells were less effective. When the dose of antigen and antiserum was increased whilst maintaining the ratio of 107 cell equivalents to 0.1 ml serum, the level of enhancement was correspondingly greater (Table 2). TNP-BALB/c cell membrane alone, at doses of 10⁵-10⁸ cell equivalents, had no effect (Table 3). Finally, it was shown that the enhanced state was strain specific. Strain A mice treated with TNP-BALB/c (H-2^d) or TNP-C57BL/6 (H-2^b) cell membrane antigen and anti-TNP serum were inoculated with P815 (H-2d) or EL-4 (H-2b) tumour cells. TNP-BALB/c membrane enhanced P815 but not EL-4 and, conversely, TNP-C57BL/6 membrane enhanced EL-4 but not P815 (Table 4).

The data therefore show that anti-TNP antibody enhances the growth of TNP-conjugated tumour cells, thus confirming the finding by Sinclair and Law¹¹, and further, that it enhances the

Tumour allograft recipients were injected i.v. with cell membrane antigen derived from 10⁷ TNP-conjugated BALB/c or C57BL/6 cells with or without 0.1 ml rabbit anti-TNP-KLH serum i.p. Mice received 10⁷ tumour cells s.c. MTA, mean tumour area estimated on day 7. Values are for groups of 7-10 mice.

growth of an unmodified tumour allograft, the enhancement being specific and mediated by TNP-alloantigen/anti-TNP antibody complexes. Because the mice were injected only once with antigen and antibody it is perhaps not surprising that growth of the enhanced tumours was generally not progressive. The proposed mechanism of this enhancement has been outlined above. Although it is possible that more than one mechanism is operative in immunological enhancement, there is substantial evidence for the participation of antigen-reactive cell opsonization by antigen-antibody complexes⁴. We have, furthermore, found that TNP-modified H-2 antigens bind specifically to lymphocytes activated specifically in mixed lymphocyte culture and that ARCs to which complexes have been bound are taken up promptly by the reticuloendothelial system when injected i.v. into normal mice¹². The experiments reported here establish the direct immunosuppressive action of such complexes in vivo.

These findings may have special significance in two fields—in tumour immunology and in organ transplantation. Tumours often express neo-determinants that are either products of their own disturbed genome or of viral origin. The experiments making use of TNP-modified antigen provide an experimental model for the latter, the hapten taking the place of virally derived determinants. The ARCO phenomenon has already been illustrated in a syngeneic tumour system, using a spontaneous reticulum cell sarcoma (RCS) in SJL/J mice^{15,16}.

Although the viral aetiology of the RCS is uncertain it is possible that antibodies against viral products were involved.

As far as tissue and organ transplantation is concerned, preliminary data indicate that the survival of normal allografts, too, can be prolonged by the administration of TNP-modified donor antigen and anti-TNP antibody (I.V.H., unpublished). This approach may be indispensable if enhancement is to be attempted in clinical organ transplantation, for the preparation of the donor membrane antigen is quick $(2\frac{1}{2}-3 \text{ h})$ and simple, and only a single antiserum directed against a well defined hapten such as TNP would be required to enhance grafts from any donor. Two further advantages would be that the antiserum can be prepared in animals or in monoclonal cell culture, thus eliminating the problem of having to prepare alloantisera in human volunteers; and that an anti-haptenic antibody, because it does not combine directly with the graft, cannot cause hyperacute rejection. Further studies on these lines are in progress.

We thank Mr R. Butler for technical assistance and the MRC for support.

Specific suppressor cells in graft-host tolerance of HLA-identical marrow transplantation

Mang-So Tsoi, Rainer Storb, Sherrie Dobbs & E. Donnall Thomas

Fred Hutchinson Cancer Research Center and Department of Medicine, Division of Oncology, University of Washington School of Medicine, Seattle, Washington 98104, USA

Graft-versus-host disease (GvHD) is a cell-mediated immunological reaction, and there is evidence in the rodent system that long-term survival without GvHD is associated with the presence of lymphocytes which specifically suppress the GvH reaction. We have accordingly developed an assay for the influence of circulating cells from patients with HLA-identical marrow grafts on the reaction of donor cells against host lymphocytes (collected before transplantation and modified by trinitrophenyl (TNP)). We find that patients without GvHD have radiation-sensitive circulating cells which specifically suppress the in vitro model of the GvH reaction. Our findings seem to have a bearing on graft-host tolerance and the causation of GvHD in vivo.

Most long-term patients after human marrow transplantation from HLA-identical siblings are healthy stable chimaeras who need no further immunosuppressive therapy^{1,2}. However, 30% of the chimaeras have mild to severe chronic GvHD characterized by lesions resembling those seen in autoimmune collagen vascular diseases^{3,4}, immunodeficiency⁵ and frequent bacterial infections⁶. We have described deposits of IgM and complement C'3 at the dermo-epidermal junction, raising the possibility that humoral anti-host immunity is involved in chronic GvHD7. The participation of cell-mediated immunity was suggested by the

	Table 1	Suppressor cell assay

Mononuclear leukocytes were separated in lymphocyte separation medium (Ficoll-Hypaque, Bionetics)^{8,10}. Host lymphocytes used as stimulating cells were cryopreserved before transplantation and thawed before use8. TNP-coupling with 10 mM trinitrobenzenesulphonic acid in phosphate-buffered saline at pH 7.4 for 10 min was done by published methods¹⁹⁻²¹. Stimulator cells were treated with 1,600 rad irradiation. Responder and suppressor cells were prepared from freshly drawn blood. The cells were finally suspended in RPMI medium with 20% male AB or pooled human male serum, 100 U ml⁻¹ penicillin and 100 µg ml⁻¹ streptomycin. From each cell suspension, 0.05 ml containing 5 × 104 lymphocytes was plated on to round-bottom plates (Linbro 76-013-05) as responder, stimulator or suppressor cells in ratios of 1:1:1. Cultures were set up in quadruplicate and incubated for 6 days at 37 °C in a humidified 5% CO $_2$ atmosphere. For the last 16 h of incubation, 2 μ Ci of ³H-thymidine (NEN) were added. The cultures were then collected and lymphoctye incorporation of the isotope-labelled thymidine was measured in a liquid scintillation counter.

% Suppression =
$$1 - \frac{\text{median c.p.m. of test cultures}}{0.5(\text{median c.p.m. of control cultures }(A + B))} \times 100$$

This formula has been described and justified¹⁰. A suppression of ≥30% was considered significant.

- * Other stimulator cells were also used (see Tables 2,3).
- † Chimaera cells = donor lymphocytes living in the marrow recipients.

	Table 2 A	n example	of results in	patient 9	87

% Suppression			94 (-20)	-4	-39	19				

A test was considered not evaluable when the MLC response of donor cells to a stimulator population was less than twice that of the autologous control. Test cultures consisted of 5×10^4 donor lymphocytes as responders, 5×10^4 stimulator cells and 5×10^4 chimaera cells as suppressors. Control culture A consisted of 2 (5×10^4) donor lymphocytes and 5×10^4 stimulator cells. Control culture B consisted of 2 (5×104) chimaera lymphocytes and 5×104 stimulator cells. % Suppression was calculated according to the formula in Table 1 except for cultures indicated (*†). The high negative suppression which occurred less frequently than positive suppression resulted from an enhanced MLC response in the mixed culture. Chimaera cells alone often showed a lower MLC response than donor cells alone. The enhancement seen in mixed culture is probably due to an increased response of chimaera cells in the presence of donor cells. Chimaera cells may lack helper cells necessary for an adequate MLC response, and these are provided by the donor cells.

- In these cultures, the chimaera cells were irradiated with 1,600 rad.
- † In these cultures, 5×10⁴ irradiated donor cells were added to the responder (donor) cells and stimulator cells. No control B was set up because irradiated suppressor cells gave no response to the stimulators.

observation of unidirectional reactivity of lymphocytes (of donor origin) from most chimaeras with chronic GvHD in response to cryopreserved host lymphocytes in mixed leukocyte culture (MLC)^{8,5}. It was tempting to speculate that this finding represented the in vitro equivalent of a continuing immunological reaction which manifested itself in vivo as chronic GvHD. Conversely, chimaeras without GvHD lacked in vivo evidence for immunological reactions, and their lymphocytes in general did not display MLC reactivity to host cells8. We have also reported the presence in patients with chronic GvHD of circulating cells that suppressed the ability of lymphocytes from the marrow donor to proliferate in response to unrelated lymphocytes and/or to concanavalin A^{10,11}. Others described abnormal

numbers of TH₂⁺ cells in some patients with GvHD¹². Studies of *in vitro* immunoglobulin synthesis showed a lack of helper cells and the presence of suppressor cells in chimaeras with chronic GvHD¹³. Such cellular imbalance may explain the severe immunodeficiency seen in patients with chronic GvHD. Stable long-term chimaeras generally did not show evidence for similar immunological deficiencies.

The mechanisms maintaining stable graft-host tolerance in healthy long-term survivors after marrow transplantation have been recently investigated. A role for serum-blocking factors has been ruled out in both canine and human recipients of marrow grafts^{14,15}. Although the involvement of specific suppressor cells in the maintenance of transplantation tolerance has been established by many investigators¹⁶, in clinical marrow transplantation, such evidence is lacking due to the difficulty of studying a model with HLA identity. In the animal models, we have presented circumstantial evidence for an active suppressor mechanism in stable canine radiation chimaeras¹⁷, and Tutschka et al. suggested that the development of specific and nonspecific suppressor cells in rat chimaeras after the resolution of GvHD accounted for the establishment of specific graft-host tolerance¹⁸.

In the present study, the in vitro model was devised to test

chimaera cells for their ability to suppress the response of donor lymphocytes to TNP-modified host cells stored before transplantation. TNP was used because donor lymphocytes did not respond to unmodified host cells in the MLC due to HLA identity. The TNP moiety of trinitrobenzene sulphonate covalently links to ε -amino groups of the lysines of cell-surface proteins. Studies in mice have shown that cytotoxic cells generated in vitro after sensitization with TNP-modified autologous cells recognize not only the TNP moiety but also self components coded for by genes mapping in H-2 (ref. 19). Studies on the human cytotoxic response to TNP-modified cells have suggested that almost half of the cytotoxicity generated was directed against polymorphic determinants thought to be HLA linked20. Some of the cytotoxic activity seemed to be directed against TNP in association with relatively nonpolymorphic antigens widely shared among humans²¹. These findings were interpreted as evidence for considerable diversity of the types of cell-surface determinants that human cytotoxic cells can recognize in association with TNP.

The hypothesis underlying the present study was that polymorphic determinants not linked with HLA can be recognized in association with TNP in a primary MLC assay and that these determinants have a role in human GvHD. We presumed that

[†] Results previously reported10.

^{*} These patients had extremely limited chronic GvHD.

suppression of the MLC reactivity by lymphocytes from the chimaeras without GvHD would be specific for recognition of TNP-associated host determinants but would not impair recognition of TNP-associated determinants shared between the siblings or with unrelated individuals. Conversely, recognition of TNP-associated determinants by donor lymphocytes would not be abrogated by lymphocytes from chimaeras with chronic GvHD.

Thirty-seven patients with aplastic anaemia, leukaemia or Hodgkin's lymphoma (Table 3), 8-50 yr old, were treated by high-dose cyclophosphamide, either alone or in combination with 1,000 rad total body irradiation, in preparation for a marrow graft from a genotypically HLA-identical sibling^{1,2}. All were given immunosuppression with intermittent methotrexate for no longer than 3 months post-grafting. Fourteen were healthy chimaeras without GvHD and 23 had minimal to severe chronic GvHD. Tests were carried out between 131 and 1,460 days post-grafting. At the time of testing six patients were under immunosuppressive treatment for chronic GvHD⁴ while the remainder were untreated.

Details of the lymphocyte separation, TNP modification and the assay system are described in Table 1 legend. Lymphocytes from 37 marrow donors were stimulated by TNP-modified lymphocytes from their recipients collected before transplantation (TNP-modified host cells) with stimulation indices (SI) ranging over 2-15.8 (mean 4.3). Mononuclear cells from the peripheral blood of the chimaeras were tested for their ability to suppress the reactivity of the donor lymphocytes to TNPmodified host lymphocytes. In addition, we tested the effect of chimaera lymphocytes on the response of the donor lymphocytes to unmodified, unrelated stimulating cells from healthy individuals ('nonspecific' suppression)10. To test for specificity, the effect of chimaera lymphocytes on the responses of the donor lymphocytes to TNP-modified donor and TNP-modified unrelated lymphocytes was also studied.

Table 2 shows an example of the results in a patient without GvHD (UPN 987) studied 362 days after transplantation. The circulating lymphocytes from the chimaera, when mixed with donor lymphocytes in an MLC, suppressed the response to TNP-modified host cells by 94%. The suppressor activity was abrogated by exposure of chimaera cells to 1,600 rad irradiation. (Radiosensitivity of the suppressor cells was also shown in four out of four other cases studied.) The chimaera's lymphocytes did not suppress the response of donor lymphocytes to TNP-modified donor nor unrelated TNP-modified or unmodified cells.

Table 3 summarizes the results in the 37 patients studied. Lymphocytes from 13 of 14 healthy chimaeras suppressed the response of donor lymphocytes to TNP-modified host lymphocytes compared with those of only 5 of 23 chimaeras with chronic GvHD (P < 0.0005, χ^2 test). Lymphocytes from none of the healthy chimaeras suppressed the ability of their marrow donor lymphocytes to respond to unmodified unrelated lymphocytes compared with those of 9 of the 22 chimaeras with chronic GvHD tested (P < 0.01). We were able to test two patients (UPNs 656 and 679) from the former group repeatedly and show comparable results. Suppression of donor lymphocyte responses to TNP-modified self and TNP-modified unrelated lymphocytes was seen in 2/7 and 1/14 cases among healthy chimaeras and in 4/14 and 3/16 cases among chimaeras with chronic GvHD (differences not significant).

The results of the study are in agreement with our hypothesis. Most patients without GvHD had circulating cells 'specifically' suppressing donor lymphocyte reactivity to TNP-modified host cells while most patients with chronic GvHD lacked specific suppressor cells. This suggests that stable graft-host tolerance after human marrow grafting is maintained by specific suppressor cells. Conversely, the lack of specific suppressor cells in patients with chronic GvHD allows an immunological reaction to occur which manifests itself in vivo as GvHD and in vitro as unidirectional reactivity of chimaera lymphocytes (that is, donor lymphocytes in the patient) against cryopreserved host lymphocytes in MLC8. The nature of these suppressor cells and the time of their appearance in the blood after transplantation are unknown.

The present study also confirms a previous observation 10,11 on the existence of another class of suppressor cells, present in patients with and absent in those without chronic GvHD, which nonspecifically suppresses the response of marrow donor lymphocytes to unmodified unrelated lymphocytes in MLC. These nonspecific suppressor cells may be one explanation for the severe immunodeficiency⁵ and the recurrent infectious complications⁶ characteristic of patients with chronic GvHD.

Human Ia molecules carrying DC1 determinants differ in both α - and β -subunits from Ia molecules carrying DR determinants

Giorgio Corte*, Franco Calabi*, Guido Damiani*, Antonio Bargellesi*, Roberto Tosit & Rosa Sorrentino‡

* Istituto di Chimica Biologica, Università di Genova, Viale Benedetto XV, 1-16132 Genoa, Italy Laboratorio di Biologia Cellulare, CNR, Rome, Italy ‡Gruppo di Microbiologia e Patologia Generale, Università di Roma, Rome, Italy

Several genetic markers of human la molecules, each recognized specific alloantisera, have been defined: 1,2,3,4,5,w6,7,w8,w9,w10. They are controlled by a single locus, HLA-DR. In addition alloantigenic specificities have been identified which are associated, at the population level, with two or more of the above DR specificities. They have been called 'supertypic specificities'. DC1 supertypic specificity (nomenclature equivalents: MB1, MT1, LB12) has attracted particular attention, because although exhibiting a population association with DR1, 2 and w6, DC1 is carried by a different molecular species¹⁻³. Possibly, DC1 may represent the first genetic marker of a locus different from the DR locus but in strong linkage disequilibrium and therefore probably closely linked to it. Here we report the development of a monoclonal reagent specifically directed against DC1 and its utilization in a structural analysis of DC1 molecules as compared with Ia molecules carrying different DR determinants.

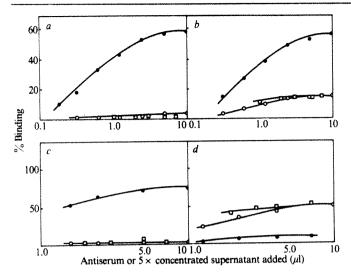

Fig. 1 A detergent-solubilized Ia preparation from the Daudi cell line was ¹²⁵I-labelled by the chloramine T method. Limited papain digestion was performed at 1:40 enzyme to protein ratio (bovine serum albumin as carrier protein) for 30 min at 37 °C. Papainunsplit' and 'papain-split' fractions were separated on a column of Biogel A 1.5 and further purified by LcH affinity chromatography. Details about the whole procedure have been previously reported8. Tests of the two fractions with the different antisera were performed by the double precipitation direct binding test1 Aliquots of antigen containing 15,000 c.p.m. were incubated with different antiserum dilutions for 16 h at 20 °C in 0.075 M Tris-HC1 buffer, pH 7.8, containing 0.2% Renex-20 detergent and 0.02% bovine serum albumin. Precipitating antiserum (either sheep antihuman or rabbit anti-mouse immunoglobulin) was then added at equivalence and the radioactivity in the washed precipitate determined. Per cent binding was expressed relative to the binding of the same antigenic preparation by a rabbit antihuman Ia antiserum. Further details are given elsewhere2. Absorption of the papain-split fraction was achieved by reacting 200,000 c.p.m. of antigen with 20 µl of either Fe131/4 or Fe88/37 alloantiserum for 16 h at 20 °C. The supernatant recovered after precipitation with sheep anti-human immunoglobulin was then further tested with the different antisera at varying dilutions. O, Fe131/4; •, Fe88/37; \square , BT3/4. a, Daudi unsplit; b, Daudi split (not absorbed); c, Daudi split (absorbed with Fe 131/4, anti-DC1); d, Daudi split (absorbed with Fe 88/37, anti-DRw6).

Table 1 Reactivity of monoclonal BT3/4 with lymphoblastoid B-cell lines and peripheral blood B cells

Lymphoblastoid B-cell lines LG2, LG17, LG28 were provided by Dr W. Leibold and were derived as previously described²⁷. All cell lines were maintained in RPMI 1640 medium supplemented with 10% fetal calf serum (Seromed). B cells were purified from peripheral blood by already described techniques²⁸. Indirect immunofluorescence was carried out as previously described²⁸.

The monoclonal antibody BT3/4 is secreted by a hybridoma obtained by the method described by Gefter et al.4. Briefly, BALB/c mice were immunized intraperitoneally at 10-day intervals with 107 E-rosetting cells obtained from a secondary mixed lymphocyte culture (MLC). A mouse was killed 4 days after the third injection and its spleen was fused with P3/X63-Ag8-U1 myeloma cells. Fourteen days after fusion the supernatant of each cell was assayed by indirect immunofluorescence on activated T cells. Positive cultures were cloned on soft agar essentially as described by Coffino et al.5, and the clone BT3/4 passed into ascites form for mass production of monoclonal IgG1. When tested on a panel of cell lines and peripheral blood lymphocytes by indirect immunofluorescence, BT3/4 invariably reacted only with lymphoblastoid B-cell lines and B lymphocytes from donors with a DR phenotype including DR 1, 2 or w6 (Table 1). The specificity of BT3/4 is similar to that previously reported^{6,7} for the monoclonal antibody Genox 353.

At the molecular level, the specificity of BT3/4 was tested on purified Ia preparations from the Daudi cell line (Drw6⁺,DC1⁺). As reported previously, after limited papain digestion, two fractions of Daudi Ia can be separated by gel filtration: 'papainunsplit' fraction, retaining the approximate size of untreated molecules, and a 'papain-split' fraction, with decreased molecular weight. DC1 molecules were present in increased proportion in the 'papain-split' fraction8. This provided a convenient test of the specificity of the monoclonal BT3/4, which, as shown in Fig. 1 (a and b) did not react with the 'papain unsplit' fraction, while reacting similarly to the reference anti-DC1 alloantiserum Fe131/4 with the 'papain-split' fraction. Moreover, the reactivity of BT3/4 was completely abolished by absorption with Fe 131/4, whereas absorption with Fe 88/37 (anti-DRw6) induced a parallel increase of binding of Fe 131/4 and of monoclonal BT3/4 (Fig. 1, c and d). This shows that the molecules which carry the DC1 determinant as recognized by a specific anti-DC1 alloantiserum are the same molecules which carry the determinant recognized by the BT3/4 monoclonal antibody.

DC1 antigen was purified by immunoabsorption to Sepharose-bound BT3/4 from the lymphoblastoid cell lines

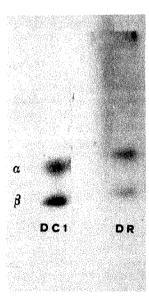

Fig. 2 Autoradiograph of a 12.5% SDS-PAGE of unreduced DC1 and DR antigens. 10^7 WT52 cells were lysed with 0.5% Nonidet P40 and centrifuged to remove nuclei and cell debris. DC1 and DR molecules were purified from the lysate by the immunoabsorption method described in detail in ref. 9. BT3/4 and PTF29 were coupled to Sepharose 4-B by the cyanogen bromide technique. A Sepharose-bound monoclonal antihuman IgE was used as control. The antigens were eluted with 5% SDS and labelled using the chloramine T method according to Greenwood et al. 29 . SDS-PAGE was carried out in slab gels using the discontinuous Tris buffer system as previously reported Non-reducing conditions were used to increase separation of α -and β -chains.

LG2 and WT52, carrying DR allospecificities 1 and w6, respectively. After iodination, the bound material was analysed in SDS-polyacrylamide gel electrophoresis (PAGE) (Fig. 2).

DC1 antigen is composed of two chains with an apparent molecular weight very similar to that of DR α - and β -chains. However, unreduced DC1 β -chain moves slightly faster than DR β -chain at an apparent molecular weight of 23,000.

The structure of DC1 antigens isolated from the two lines was further compared by two-dimensional peptide mapping with that of DR 2, 5, w6 and 7 similarly purified with the monoclonal PTF 29.12 (ref. 9). Figure 3 shows the comparison between peptic digests obtained from α chains of the two DC1 preparations and of the four DR antigens; DC1 α -chains isolated from DR 1 and DR w6 cell lines are identical, but bear no resemblance to any of the four DR α -chains. In Fig. 4 the equivalent comparison is reported for DC1 and DR β -chains. As previously reported, the maps of the β -chains from the four different DR alleles show, besides the expected degree of allotypic variability, a core of 12 invariant peptides; none of these peptides is present in the DC1 β -chain. Again β -chains of DC1 purified from the DR 1 and DR 6 cell lines are identical.

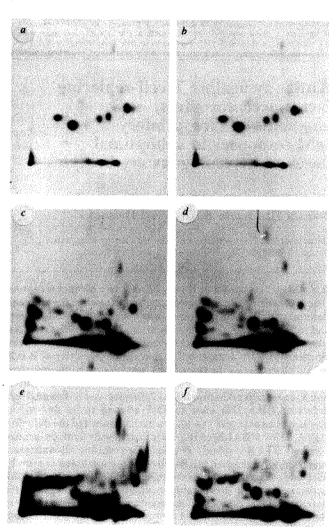

Fig. 3 Autoradiographs of peptide maps of ¹²⁵I-labelled α-chains of DC1 and DR antigens. α- And β-chains were eluted from the gel and processed for peptide mapping as previously described. Briefly, after complete reduction with dithiothreitol and alkylation with iodoacetamide, α- and β-chains were digested with pepsin (1;50 enzyme to protein ratio, 18 h at 37 °C in 100 μl of formic acid/acetic acid/water (1;4;45)). Two-dimensional peptide maps were obtained by a technique based on the method of Feinstein α, DC1 α-chain from LG2 (DR1, 1); b, DC1 α-chain from WT52 (DRW6, W6); c, DR α-chain from WT52; d, DR α-chain from IBW9 (DR7, 7); e, DR α-chain from LG17 (DR2, 2); f, DR α-chain from WT48 (DR5,5).

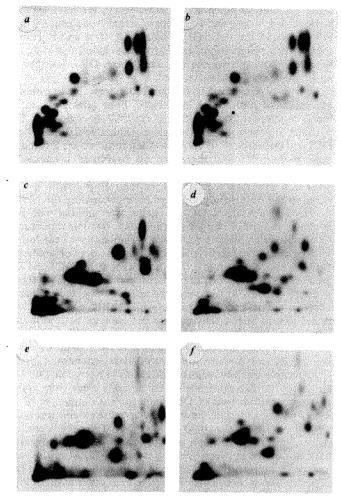

Fig. 4 Autoradiographs of peptide maps of 125 I-labelled β chains of DC1 and DR antigens. a, DC1 β -chain from LG2 (DR1, 1); b, DC1 β -chain from WT52 (DRw6, w6); c, DR β -chain from WT52; d, β -chain from IBW9 (DR7, 7); e, DR β -chain from LG17 (DR2, 2); f, DR β -chain from WT48 (DR, 5). The detailed comparison of DR chains from different alleles is given elsewhere. DR peptide maps similar to those shown in ref. 9 have been included here to facilitate comparison with the peptide maps of DC1 chains.

It should be stressed that this type of technique, involving comparison of molecules labelled in a single amino acid, underestimates the degree of homology of their primary sequences. In fact, a single amino acid substitution is sufficient to cause a peptide to move to a different position. However, it can be safely concluded that DR and DC1 differ both in their α - and β -chains and that the minimum number of different amino acids corresponds to the number of spots present in the maps (α and β respectively). A precise quantitation must await sequence data.

The data presented are better discussed in their possible analogies to the murine Ia system. Murine Ia includes at least two subsets of molecules with similar basic structures: I-A molecules and I-E molecules. Based on recent data 10,11 , the A α - and A β -subunits as well as the E β -subunit are controlled by genes in the I-A subregion, whereas the E α -subunit maps in the I-E subregion. Polymorphic structural differences can be detected mainly on the three I-A subregion-controlled subunits. Several structural and serological findings, including amino acid sequence data, indicate homology between murine I-E molecules and 'human Ia molecules' 12,13 . These data were obtained before the recognition of separate subsets of Ia molecules probably controlled by different loci 1,14,15 . Therefore it is very likely that the major molecular subset, that is, the DR locuscontrolled molecules, were actually tested. In fact, DC1 molecules constitute a minor fraction as compared with DR molecules and their presence would not have affected the

sequence analysis much above 'noise level'. We have actually shown that a mouse anti I-E^k alloantiserum could actively bind DR molecules but not DC1 molecules (R. Tosi and P. Ivanyi, unpublished observation). It must be concluded that only the homology between murine I-E and human DR-controlled Ia molecules is clearly demonstrated.

Thus it is possible that DC molecules may be the human equivalent of murine I-A molecules. Four analogies can be found to support this hypothesis: (1) DC1 β -chains and DR β -chains are controlled by very closely linked loci. In fact, both DC1 and DR serologically detected determinants are located on their β -chains^{1,15} and there are no confirmed instances of DC/DR recombination. (2) A β -chains have been shown to possess a lower molecular weight than E β -chains¹⁶. This parallels the observation reported here concerning the migration in SDS-PAGE of DC1 β-chains as compared with DR β -chains. (See ref. 15 for a discussion of the possible significance of this size difference.) (3) Extensive variations have been found, both by limited sequence analysis 12,17 and by peptide analysis 18 between murine A α and E α . Our data show that DC1 and DR molecules differ not only, as expected, in their β -chains, but also in their α -chains. (4) A monoclonal antibody directed against an allotypic specificity of rat Ia molecules, MRC OX3, was also found to recognize a polymorphic determinant both in mouse and in man^{19,20}. In man, it reacted only with DR 1, 2 or w6 positive cell lines, thus behaving as an anti-DC1. In the mouse, it recognized an I-A subregion-controlled determinant.

The above are only indirect indications of a possible DC/I-A homology. A direct demonstration can only come from amino acid sequence analysis of DC1 molecules. Comparison of α chains will be especially informative as these exhibit less polymorphic variations than do β -chains¹². Whatever the homology between single human and murine Ia loci, the data suggest a basic similarity between the two systems. Both murine and human Ia molecular pools can be subdivided into at least two subsets which substantially differ from each other both for their α - and β -chains. A similar conclusion has been reached for rat In antigens²¹. The association of DC1 β -chains with a distinctive species of α -subunit definitely rules out the possibility that the DC1 supertypic specificity is controlled by the HLA-DR locus. In fact, the different DR allelic products have been shown to possess marked structural variations in their β -subunits but not in their α -subunits ^{9,22,23}, while the structure of the α -subunit associated to the DC1 molecule has clearly distinctive features. This confirms previous immunochemical and genetic data which assigned DC1 to a separate, non-DR, locus.

An interesting point, as in the mouse system, is the noninterchangeability of α -chains in their association with β -chains encoded by different loci. This is probably due to a selective post translational association, as coordinated translation of α -and β -chains from the same messenger seems unlikely because separate messenger RNAs for the two chains can be isolated²⁴, and because A β -chains can associate with A α -chains transmitted by the homologous chromosome²⁵. Markert and Cresswell²⁶ have recently reported the existence of at least two species of β -subunits and at least three species of non-interchangeably associated α -subunits. Apart from the interpretation given by the authors on the localization of alloantigenic determinants on the different chains, the above data, in agreement with ours, also imply the existence in man of Ia molecular subsets differing for both α - and β -chains and carrying alloantigenic determinants which are transmitted in strong linkage disequilibrium with DR determinants.

Antibody against T cell-replacing factor acceptor site(s) augments in vivo primary IgM responses to suboptimal doses of heterologous erythrocytes

Kiyoshi Takatsu, Yoshimi Sano, Shohken Tomita, Noboru Hashimoto & Toshiyuki Hamaoka

Department of Oncogenesis, Institute for Cancer Research, Osaka University Medical School, Osaka 553, Japan

It is widely accepted that B cells possess two distinct receptors. One is the surface immunoglobulin that recognizes the antigenic determinant; the other transmits the signals for proliferation and differentiation of the B cells after receiving differentiation stimuli mediated by a soluble factor derived from helper T cells. Previously¹⁻⁴, we demonstrated that the responsivity of B cells to T cell-replacing factor (TRF) was under X-chromosome control, as determined by genetic analysis of the TRF-nonresponsiveness of B cells from DBA/2Ha mice. An X-linked B-cell defect of DBA/2Ha mice to TRF seemed to be due to the absence of an acceptor site(s). We have immunized the defective $(DBA/2Ha9 \times BALB/c\delta)F_1$ male mice with antigen-primed parental BALB/c splenic B cells. The resulting alloantiserum preferentially inhibited the B-cell response mediated in vitro by TRF added continuously to the culture. We report here that this antiserum, which presumably contains antibody against the putative TRF-acceptor site, augments primary IgM responses to simultaneously administered suboptimal doses of heterologous erythrocytes injected into TRF high-responder animals. These augmented IgM-PFC (plaque -forming cell) responses were also observed in other X-linked B-cell defective CBA/N mice, but not in TRF low-responder DBA/2Ha mice, suggesting that the putative TRF-acceptor site(s) functionally detectable by this antiserum is distinct from the Lyb 3 and Lyb 5 components.

To prepare alloantiserum containing anti-TRF-acceptor site(s) antibody, (DBA/2Ha×BALB/c)(DC)F₁ male mice responder animals) were immunized intra-(TRF-low peritoneally (i.p.) with splenic B cells (2×107) from DNP (dinitrophenyl)-KLH (keyhole limpet haemocyanin)-primed BALB/c mice of a high TRF-responder parental strain, with

Table 1 Enhancing activity of (DC)F₁ male anti-BALB/c B-cell antiserum on PFC responses in BALB/c and BALB/c nu/nu mice stimulated with graded doses of SRBC

BALB/c or BALB/c nu/nu mice, aged 5-7 weeks, were immunized i.v. with various amounts of SRBC in combination with $(DC)F_1$ male anti-BALB/c antiserum (1:40) or control serum, in a volume of 0.2 ml. PFC responses 4 days after antigen stimulation and antiserum injection are shown. Results are expressed as geometric means \pm s.e.m.

4 mg aluminium hydroxide gel and Bordetella pertussis vaccine (1×10^9) , followed by i.p. injection of DNP-primed B cells without adjuvant once a week for 5 weeks. Seven days after the final immunization, each mouse was partially bled once a week for 4 weeks and the serum pooled. The activity of the antiserum was determined by measuring the inhibition of TRF-mediated antibody response according to methods used elsewhere.

To determine whether the reaction of the TRF acceptor on the surface of the B cells with anti-TRF acceptor antibody altered the immune reactivity of these cells, we examined the PFC responses of BALB/c mice on stimulation with 1×10^6 sheep red blood cells (SRBC) alone or in combination with graded doses of anti-TRF acceptor site antiserum or control serum. As shown in Fig. 1, mice stimulated with SRBC alone or in combination with control serum produced ~ 500-1,500 PFCs per spleen (5-10 PFCs per 10⁶ cells), whereas mice injected with SRBC and an optimal concentration of anti-TRF acceptor site antiserum produced a 5- to 10-fold increase in anti-SRBC PFCs. Studies of the time course of this enhancing effect of the antiserum revealed that the peak response occurred on day 4 after antiserum injection in combination with a suboptimal dose of SRBC, and that by day 8 this response had declined to control serum levels (data not shown). Mice injected with (DC)F₁ male anti-BALB/c B-cell antiserum alone without antigen also produced much fewer (1.5-1.8 times the background) but significant PFC responses to SRBC. This increase in PFCs due to the antiserum was observed in anti-HRBC (horse red blood cell) plaques as well (data not shown). These findings suggest that the anti-TRF acceptor antiserum acts synergistically with antigen to produce enhanced antigen-specific PFC responses. However, this does not exclude the possibility that anti-TRF-acceptor antibody alone induces polyclonal B-cell activation.

To demonstrate that the enhancing effect of (DC)F₁ male anti-BALB/c B-cell antiserum on the PFC response of BALB/c mice is particularly evident when the triggering signals provided by both antigen and helper T cells are relatively low, we examined the effect of anti-TRF-acceptor antiserum: (1) in the presence of decreased concentrations of antigen, and (2) in the absence of T cells. Addition of antiserum (Table 1) markedly enhanced the PFC response to low doses of SRBC from 1×10^3 to 1×10^6 . In contrast, the enhancing effect of antiserum on PFC responses of those mice stimulated with large doses of SRBC was marginal. In a further experiment, the ability of (DC)F₁ male anti-BALB/c B-cell antiserum to substitute for helper T-cell activity in the induction of a primary PFC response was tested in nu/nu mice. BALB/c nu/nu mice produced a low number of anti-SRBC PFCs after priming with 1×106 SRBC plus control serum, compared with the IgM anti-SRBC PFC response of BALB/c mice in the same experimental conditions. However, the administration of (DC)F₁ male anti-BALB/c B-cell antiserum with SRBC to these nu/nu mice resulted in a striking increase in anti-SRBC PFC responses (Table 1).

It has been reported that CBA/N mice lack a subpopulation of B cells that appears late in ontogeny⁵⁻⁷ and responds to

thymus-independent type 2 antigens, such as Ficoll and dextran^{2,9}. As the defect is X-linked and recessive, an alloantiserum denoted anti-Lyb 3 that would react exclusively with this subset of B cells in all mouse strains except CBA/N was raised by immunizing (CBA/N×BALB/c)F₁ male mice with BALB/c spleen cells³. Huber et al.⁵ demonstrated that this anti-Lyb 3 antiserum acts synergistically with antigen to produce enhanced antigen-specific PFC responses in various strains of mice except CBA/N. We decided to test whether this augmenting effect of (DC)F₁ male anti-BALB/c B cell antiserum is due to an interaction between antibody and TRF-acceptor sites on the surface of B cells, and also to test whether or not the TRF-acceptor sites detected by this antibody are identical to or closely associated with the Lyb 3 molecules. We examined the effect of (DC)F₁ male anti-BALB/c B-cell antiserum on primary anti-SRBC

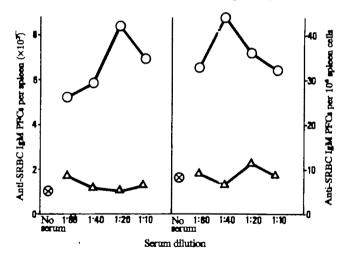

Fig. 1 Dose-related augmenting effect of (DC)F₁ male anti-BALB/c B-cell antiserum on anti-SEBC PFC responses. (DBA/2Ha×BALB/c)(DC)F₁ male anti-3ALB/c B-cell alloantiserum containing anti-TRF-acceptor site antibody was prepared by the method described elsewhere². Briefly, after treatment with monocional anti-Thy 1.2 antiserum and complement, splenic B cells from DNP-KLH-primed B cells of mice of a high TRFresponder strain (BALB/c) were used as immunizing cells. Low TRF-responder (DC)F₁ male mice were injected i.p. with these DNP-primed B cells (2×10^7) , with 4 mg aluminium hydroxide gel and B. pertussis vaccine (1×10^7) , followed by i.p. injections of DNP-primed B cells without adjuvant once a week for 6 weeks. Seven days after the final immunization, partial bleeding was performed on each mouse once a week for 4 weeks and the serum pooled. Six-week old BALB/c mice were immunized i.v. with 1×10^6 SRBC alone (\otimes) or in combination with varying dilutions of (DC)F₁ male anti-BALB/c B-cell antiserum (O) or normal (DC)F₁ mouse serum (Δ) as a control, in a volume of 0.2 ml. After 4 days the mice were killed and the number of IgM plaque-forming cells (PFC) to SRBC was determined per spleen and per 10° spleen cells. Each point represents the mean PFC response of six mice from a representative experiment of a series of five.

Table 2 The effect of (DC)F₁ male anti-BALB/c B-cell antiserum on various strains of mice

Strain	Serum	Direct PFCs per spleen	Direct PFCs per 10 ⁶ spleen cells
BALB/c	Control	518 (1.09)	4.31 (1.17)
•	(DC)F ₁ (3)anti-BALB/c	7,590 (1.23)	42.5 (1.24)
C57BL/6	Control	649 (1.28)	7.10 (1.27)
•	(DC)F ₁ (3)anti-BALB/c	3,934 (1.09)	39.0 (1.02)
DBA/2Ha	Control	104 (1.44)	1.48 (1.22)
•	(DC)F ₁ (3)anti-BALB/c	326 (1.33)	1.78 (1.29)
CBA/N	Control	165 (1.37)	3.30 (1.44)
•	(DC)F ₁ (3)anti-BALB/c	3,030 (1.03)	73.6 (1.12)

Various strains of mice, aged 6-8 weeks, were immunized i.v. with 1×10^6 SRBC in combination with (DC)F₁ male anti-BALB/c antiserum (1:40) or control serum, in a volume of 0.2 ml. Results are expressed as geometric means ± s.e.m.

responses in various strains of mice. As shown in Table 2, enhancement of anti-SRBC responses was observed not only in BALB/c but also in C57BL/6 and CBA/N mice. In contrast, intravenous (i.v.) injections of varying doses of anti-TRF acceptor serum failed to augment the anti-SRBC PFC response in DBA/2Ha mice, indicating that the augmenting effect was clearly due to a specific reaction of this antiserum with a component which is absent from the DBA/2Ha mice (Table 2). The fact that injection of CBA/N mice with SRBC in combination with antiserum produced more than a 10-fold increase in anti-SRBC PFCs indicated that enhancement of the anti-SRBC responses in CBA/N mice is clearly due to a specific reaction of this serum with a component that is different from Lyb 3 and Lyb 5, which are absent from CBA/N mice.

Our results clearly demonstrate that passive administration of anti-TRF acceptor site antiserum in combination with suboptimal doses of SRBC in TRF high-response animals can induce augmented primary anti-SRBC IgM responses (Fig. 1 and Table 2), and that stimulation of the acceptor site(s) on antigenreactive B cells with antibody allows more efficient triggering of B cells by antigen. The ability of anti-TRF acceptor site antibody to substitute for helper T-cell activity in the induction of a primary response is obvious from the fact that anti-TRF acceptor site antiserum administered to nu/nu mice resulted in the production of a significant PFC response (Table 1). Although the positive response of CBA/N mice to (DC)F₁ male anti-BALB/c B-cell antiserum supports the notion that the TRFacceptor site(s) which we detected here is different from Lyb 3 (and -5 and -7) components, another possibility is that there are several (at least more than one) kinds of TRF-acceptor site molecules on B cells, especially in the light of reports by Parker et al. 10 and Ahmed et al. 11 on the inability of unprimed B cells from CBA/N mice to respond to TRF (concanavalin A (Con A) supernatant). As anti-Lyb 3 antiserum was also able to augment a primary anti-SRBC response in vivo to suboptimal doses of antigen, and thus showed the same functional characteristics as our antiserum, Lyb 3 could be another acceptor molecule for the TRF originated from Con A supernatant. The interrelation between the TRF acceptor site(s) detected here and its Lyb 3 components awaits further investigation.

Note that there is a discrepancy between the triggering effect of anti-TRF acceptor antibody as described here and the inhibitory effect of the same antibody on B cell-triggering mediated by TRF as described previously²⁻⁴. Recently, we found that antigen-primed B cells could be triggered in vitro by anti-TRFacceptor antibody when the cells were pulsed with the antibody before the culture, whereas continuous presence of the antibody never triggered the B cells, and resulted in the inhibition of B-cell triggering mediated by TRF (to be published elsewhere). Therefore, this discrepancy in the effect of the antiserum may be explained by the dose of antiserum present in the critical period of B-cell triggering. Figure 1 shows that, in in vivo conditions the B-cell responses were greater at lower concentration (1:20) than at higher concentration (1:10), and an optimal concentration of antibody was required to trigger the B cells. This may be due to the generation of similar experimental conditions in vivo to those in the antibody-pulsing of B cells in vitro. However, this notion does not necessarily exclude other possibilities such as difference in effect of antibodies of various classes contained in the antiserum or difference in threshold of various B-cell subsets (antigen-primed B cells as opposed to non-primed B cells) to be stimulated by the antibody.

Although further investigation is required, such an alloantiserum containing anti-TRF-acceptor antibody may provide us with the experimental strategy necessary for characterization of the TRF-acceptor site on B cells and for analysis of the fine mechanism of B-cell triggering through this site.

This work was supported by a grant-in-aid for scientific research from the Japanese Ministry of Education, Culture, and Science, the 1980 Naito Research Grant and a grant from the Osaka Foundation for Promotion of Clinical Immunology. Phylogenetic tracing of Ia genes

The I region of the mouse H-2 complex has been subdivided into five subregions (A, B, J, E, C) on the basis of serological and functional analyses of intra-MHC (major histocompatibility complex) recombinant strains1. However, no serologically detectable specificities nor Ir genes have been localized to the I-E subregion of the $H-2^b$ and $H-2^s$ haplotypes. Attempts to identify I-E gene products of these haplotypes by chemical analyses have also been unsuccessful^{2,3}. Thus, the H-2 complex of these haplotypes seems not to express I-E subregion genes. In this case, alloantisera raised in 'I-E-negative' strains of mice against 'I-E-positive' mouse cells might contain, in addition to the usual alloantibodies, antibodies reactive with conserved portions of I-E molecules inherited from a hypothetical primordial gene $(I-E_0)$ which may have existed long before the speciation of contemporary animals. Such antibodies would show extensive cross-reactions with the I-E homologues of various species of animals. Interspecies cross-reactions of anti-Ia mouse alloantibodies have indeed been observed. Although such a cross-reaction was first found between mouse I-A and rat Ia-homologues, subsequent studies indicated much broader and more frequent interspecies cross-reactions of anti-I-E antibodies4-8. We have now expanded the demonstration of such interspecies cross-reactions to submammalian vertebrates. The possible basis of these unusual cross-reactions and its phylogenetic implication will be discussed.

351

Fig. 1 Cross-reaction of anti-Ik mouse alloantibody with lymphocytes of submammalian species. Reactivity of the antiserum was assessed by two-stage Trypan blue cytotoxicity assay using rabbit complement. When necessary, rabbit complement was preabsorbed with crythrocytes of the testing animal. Absorption of the antiserum with mouse spleen cells was performed by incubating the 1:10 dilution of the serum with 1×10^9 cells per ml for 1 h on ice. The completion of the absorption was confirmed by cytotoxicity assay on cells of the absorbing strain. Frog spleen cells were selected for adherence to nylon fibre in an attempt to enrich Ia-positive cells. Cytotoxicity curves of an A.TH anti-A.TL antiserum absorbed with: no cells (○), B10.BR (□), B10.D2 (●), B10 (△), B10.A (▲), B10.A(2R) (■), B10.A(3R) (*) and $B10.A(4R)(\times)$.

The present study used an A.TH anti-A.TL antiserum (serum 201) which is specific for the entire I region of the k haplotype. This antiserum showed cross-reactivity on lymphocytes of various mammalian species (data not shown). Further examination of the cross-reactivity of serum 201 on chicken and frog (Rana catesbelana) lymphocytes revealed that the cross-reac-

See Fig. 1 legend for details.

tion extended even to submammalian species (Fig. 1). The cytotoxicity of the antiserum on these cells was not due to contaminating natural antibodies, as B10.BR (H-2k) cells completely absorbed the cytotoxic antibodies in both cases (Fig. 1). Likewise, B10.D2 and B10.A cells absorbed the antibodies whereas B10 cells did not. Absorption of serum 201 with B10.A(2R) and with B10.A(3R) cells eliminated the crossreactive antibodies, placing the gene encoding the cross-reactive antigen between the I-J and D regions (Fig. 1, Table 1). This result was corroborated by the failure of B10.A(4R) cells to absorb the cross-reactive antibodies. These results were identical to those observed for a variety of mammalian lymphocytes.

To confirm these findings, mouse antisera raised against various non-mammalian vertebrates such as chicken, frog and fish (Carassius carassius) were tested for reactivity on mouse lymphocytes. As shown in Table 2, all three antisera raised in I^* mice against non-mammalian lymphocytes showed cross-reactions on B10.BR cells. Reactivity of these antisers on A.TL and B10.S(9R) cells located the gene encoding the cross-reactive antigen between the I-B and D regions. These results not only confirmed the specificity of the cress-reactions detected by serum 201 but also indicated that even fish lymphocytes express molecules cross-reactive with $I-E/C^{I}$ gene products.

It has already been shown in several mammalian species that the cross-reactive antigens are homologues of murine Ia antigens—glycoproteins consisting of two polypeptide chains (molecular weights 35,000 and 28,000) which are encoded by MHC-linked genes⁶⁻¹⁰. Thus, it seems quite likely that the

cross-reactive antigens of other species are also homologues of the murine Ia molecules. The I-A- and the I-E-subregion genes in the mouse seem to have essentially overlapping functions. Although we do not know the exact nature of the functions of these genes, the I-E gene seems to be functionally dominant in the mouse, as judged from the extent of the alloantigeneic polymorphism and the number of Ir genes mapped to these subregions. Such functional dominance of the I-A subregion in this species may account for the apparent non-catastrophic loss of I-E antigens in some mouse strains. From these studies, the origin of the $I-E_0$ gene has been traced back at least to fish. This cross-reactive anti-Ia antibody may thus prove to be a powerful probe with which to study the evolutionary significance of Ia molecules and Ia-bearing cells in the immune system.

Measurement of circulating prostacyclin

R. J. Haslam & M. D. McClenaghan

Department of Pathology, McMaster University, Hamilton, Ontario, Canada L8N 3Z5

Prostacyclin (PGI₂) is a potent inhibitor of platelet aggregation and a vasodilator that is synthesized from prostaglandin endoperoxides by vascular endothelial and smooth muscle cells^{1,2}. Its action on platelets is mediated by cyclic AMP3-5. Circulating PGI₂ has been detected through its inhibitory effect on the accumulation of platelets on collagen strips superfused with blood from anaesthetized and heparinized cats⁶ and rabbits⁷ and this led to the suggestion that PGI2 is released continuously into blood passing through the lungs and functions as a circulating hormone that regulates platelet aggregability 6-9. Because of its chemical instability, no more sensitive method of detecting circulating PGI₂ has been developed and there is doubt over whether PGI₂ is present in more physiological conditions^{10,11}. Although 6-keto-PGF_{1 α}, the stable non-enzymatic breakdown product of PGI₂, has been assayed in human^{12,13} and rabbit^{14,15} plasma, uncertainty over the fraction present as PGI2 in the circulation has limited the value of the results obtained. Finally, it has been suggested that 6-keto-PGE1, a metabolic product of PGI_2 or 6-keto- $PGF_{1\alpha}$ that can inhibit platelet aggregation 16,17, may also function as a circulating hormone 18. To resolve these uncertainties, we have now developed a sensitive bioassay for PGI2-like compounds in blood. The results indicate that fresh arterial blood from physiologically normal rabbits contains insufficient PGI2 or 6-keto-PGE1 to affect platelet function.

Our assay is based on measurement of the increases in platelet ³H-labelled cyclic AMP that occur on addition of platelets containing ³H-labelled adenine nucleotides to blood. The ³Hlabelled cyclic AMP formation attributable to PGI3-like compounds in the blood was identified using an antibody that bound them. Inclusion of 1 mM 3-isobutyl-1-methylxanthine (IBMX) in the reaction mixture to inhibit platelet cyclic AMP phosphodiesterase enhanced the sensitivity of the assay about 10-fold. After addition of labelled platelets to citrated rabbit blood containing 1 mM IBMX, the increase in platelet ³Hlabelled cyclic AMP was linear with respect to time for 0.5-1.0 min, whether PGI₂ was present or not, thus providing a measure of platelet adenylate cyclase activity. When blood was preincubated at 37 °C for >1 h to remove any endogenous PGI₂, IBMX increased the platelet ³H-labelled cyclic AMP content from a basal value of $0.024 \pm 0.002\%$ of platelet ³H to $0.070 \pm$ 0.004% in 0.5 min (means \pm s.e.m., n = 30). Double reciprocal plots of the additional increases caused by exogenous PGI₂ against the PGI₂ concentration (10-1,000 pmol ml⁻¹) were linear, suggesting a single population of functional PGI₂ receptors. Computer analysis using a weighted least squares method¹⁹ gave a $K_{\rm m}$ value for PGI₂ of 29.9 ± 2.6 pmol ml⁻¹ and a $V_{\rm max}$ for the PGI₂-stimulated conversion of platelet ³H-labelled adenine nucleotides to cyclic AMP of $3.7 \pm 0.1\%$ in 0.5 min (means \pm s.e.m. from five experiments). For 6-keto-PGE₁, a K_m of 101 ± 25 pmol ml⁻¹ and a V_{max} of $3.2 \pm 0.6\%$ were obtained (means ±s.e.m. from four experiments). However, when using the formation of ³H-labelled cyclic AMP to assay amounts of PGI₂ or 6-keto-PGE₁ less than 5 pmol, we have found it most convenient to calculate experimental values from linear regressions of log $[\Delta^3H$ -labelled cyclic AMP] on log $[PGI_2]$ or log

Fig. 1 Increases in ³H-labelled cyclic AMP in labelled platelets added to blood containing IBMX and either PGI₂ or 6-keto-PGE₁; antagonistic effects of antibody prepared against 6-keto-PGF1a. Washed rabbit platelets were prepared using blood from pentobarbital-anaesthetized animals by a modification of the method of Ardlie et al. 31. After the first wash the platelets were resuspended at 2.5×10^9 ml⁻¹ in Ca²⁺-free Tyrode's solution containing 5 mM PIPES buffer, pH 6.5, and were incubated with 2 μM [2,8-3H]adenine (34 Ci mmol⁻¹, ICN) for 90 min at 20-22 °C. Almost complete uptake of the 3H-adenine occurred. The labelled platelets were then isolated by centrifugation and resuspended at 2.5 × 109 ml⁻¹ in Tyrode's solution containing 0.35% (w/v) bovine serum albumin, 5 mM HEPES buffer, pH 7.4, and an apyrase concentration (~30 µg ml⁻¹) capable of degrading 100 µM ADP at 0.1 µmol min⁻¹ at 37 °C. This suspension was stored at 37 °C in a sealed tube and was usable for up to 3 h. Blood (13.5 ml) for assay of added prostaglandin standards was withdrawn from the central artery of the ear of an unanaesthetized rabbit into a syringe containing 1.5 ml of 3.8% (w/v) trisodium citrate and was incubated in a sealed tube at 37 °C for 1 h to allow time for complete breakdown of any endogenous PGI2. Incubation mixtures (0.5 ml) were then constituted as follows: 0.4-ml samples of preincubated citrated blood were mixed with 0.5 µmol of IBMX in 0.04 ml of 0.154 M NaCl and with 0.02 ml of 0.154 M NaCl with or without y globulin (60 µg) from rabbits immunized against 6-keto-PGF_{1α} (ref. 10). Prostaglandin standards (0-5 pmol) in 0.02 ml of 0.139 M NaCl containing 9.4 mM Na₂CO₃ (PGI₂) or of 0.154 M NaCl (6-keto-PGE₁) were then added and exactly 0.1 min later 0.04 ml of the suspension of labelled platelets (1-1.5 µCi ³H) was introduced. Incubations were continued for 0.5 min at 37 °C, at which time the reactions were stopped by addition of 1.0 ml of ice-cold 15% (w/v) trichloroacetic acid and 1,000 d.p.m. of ¹⁴C-labelled cyclic AMP (28 mCi mmol⁻¹, Amersham). Each incubation was performed in triplicate. The acidified samples were centrifuged and the acid extracts applied to columns (15×0.7 cm) containing 1.5 g alumina (WN-3, Sigma) that had been washed with 10% (w/v) trichloroacetic acid. The columns were then washed with 9 ml of 10% (w/v) trichloroacetic acid, 9 ml of water and 2 ml of 0.2 M ammonium formate (pH 6.0) and cyclic AMP was eluted with a further 3 ml of 0.2 M ammonium formate³². The eluates were applied to columns containing 1.5 ml (packed volume) of Dowex 50 resin (Bio-Rad AG 50W-X8, 100-200 mesh, H* form). These columns were then washed with 6 ml of 1 mM potassium phosphate buffer, pH 7.3, and cyclic AMP was finally eluted in a further 9 ml of the same buffer which was lyophilized and counted for ³H and ¹⁴C by liquid scintillation. After correction for the recovery of ¹⁴C-labelled cyclic AMP (50-70%), platelet ³H-labelled cyclic AMP was expressed as a percentage of the total platelet ³H. a, log/log plots of the increases in platelet ³H-labelled cyclic AMP caused by different amounts of PGI₂ (●) or 6-keto-PGE₁ (■) present in blood samples also containing IBMX. b, ³H-labelled cyclic AMP (mean values \pm s.e.m., n = 3) found in labelled platelets incubated with rabbit blood containing IBMX and the indicated amounts of PGI2 or 6-keto-PGE1 either without (unshaded) or with (shaded) antibody. The results shown in a and bare from different experiments.

Table 1 Arterial concentrations of PGI₂ after intravenous injection of PGI₂ or angiotensin II

Compound injected	Time of PGI ₂ measurement (min)	Arterial PGI ₂ (pmol ml ⁻¹)	PGI ₂ remaining in blood (% of that injected)
PGI, (1 nmol per kg)	-5	$0.06 \pm 0.01(4)$	
	+2	$1.55 \pm 0.18(4)$	9.7 ± 1.1
	+5	$0.19 \pm 0.02(4)$	0.9 ± 0.1
	+10	$0.09 \pm 0.01(4)$	0.2 ± 0.1
Angiotensin II	+2	$7.55 \pm 0.37(4)$	
(5 nmol per kg)	+5	$1.53 \pm 0.37(3)$	
(+10	$0.26 \pm 0.03(3)$	
	+30	$0.03 \pm 0.01(3)$	

Values for PGI₂ are means \pm s.e.m. of the number of unanaesthetized male rabbits indicated in parentheses. The rabbits received single intravenous injections of 3–5 μ M PGI₂ in a solution containing 0.139 M NaCl and 9.4 mM Na₂CO₃ or of 20 μ M angiotensin II in 0.154 M NaCl. Arterial blood (13.5 ml) for measurement of the effects of standard amounts of PGI₂ on labelled platelets (as in Fig. 1a) was taken from each rabbit 60–90 min before injection of compound and further 2.7-ml samples for immediate assay of circulating PGI₂ were taken at the times indicated with respect to injection of compound (from progressively more proximal segments of the central arteries of the ears). The per cent of injected PGI₂ remaining in the blood (means \pm s.e.m.) was calculated on the approximate assumption that this compound was homogeneously distributed throughout a blood volume of 65 ml per kg. In control experiments, injections of vehicle did not affect arterial PGI₂ levels. Addition of angiotensin II (5–50 pmol) to assays had no effect on the increase in platelet ³H-labelled cyclic AMP caused by PGI₂ (2 pmol).

[6-keto-PGE₁] (Fig. 1a); for these regressions r^2 usually exceeded 0.99. The smallest amount of PGI₂ added to 0.5-ml assay mixtures (see Fig. 1 legend) that significantly increased platelet ³H-labelled cyclic AMP above the values obtained with IBMX alone was 0.02 pmol (average increase 0.009% of the platelet ³H). With <5 pmol per assay, amounts of 6-keto-PGE₁ four- to fivefold larger than PGI₂ were required to induce equivalent increases in platelet ³H-labelled cyclic AMP (Fig. 1a).

The y-globulin fraction from rabbits immunized with 6-keto-PGF₁₀ conjugated to bovine serum albumin has been shown to block the inhibition of platelet aggregation by PGI₂ (ref. 10). We found that inclusion of 60 µg of a comparable antibody preparation in assay mixtures containing rabbit citrated blood prevented the increases in platelet 3H-labelled cyclic AMP caused by ≤ 0.5 pmol of PGI₂ and inhibited the effects of 2 pmol of PGI₂ by >90% (Fig. 1b). Antibody to 6-keto-PGF_{1 α} also suppressed the increases in platelet cyclic AMP caused by ≤5 pmol of 6-keto-PGE₁. That these actions of the antibody preparation were due to its ability to bind PGI2-like compounds rather than to a nonspecific effect on platelet adenylate cyclase activity was established by the observation that its effects were blocked by addition of >100 pmol of 6-keto-PGF_{1a} to the assay. To distinguish between PGI2 and 6-keto-PGE1, use was made of a marked difference in their stability in citrated blood. Assays (for example, Fig. 2) showed that the activity of PGI₂ added to citrated rabbit blood (pH 7.6-7.8) decreased exponentially with a half life of 9.3 ± 0.6 min (mean \pm s.e.m., n = 6), whereas that of 6-keto-PGE₁ declined with a half life of >40 min.

To measure PGI₂-like compounds in circulating rabbit blood, 2.7 ml was rapidly withdrawn from the central artery of the ear into a syringe containing 0.3 ml of 3.8% (w/v) trisodium citrate. Citrated blood (0.4 ml) was then pipetted into tubes holding 0.5 µmol of IBMX with antibody (three tubes) and without antibody (three tubes). Labelled platelet suspension was added immediately and the mixtures (0.5 ml) were incubated for 0.5 min at 37 °C before extraction of ³H-labelled cyclic AMP (see Fig. 1 legend). All six incubations were completed within 2.5 min of arterial puncture, so that breakdown of PGI₂ had little effect on the results. The presumptive PGI₂ present in freshly taken blood was calculated from the difference between the mean values for the platelet ³H-labelled cyclic AMP formed in the presence and absence of antibody and that formed in preincubated blood from the same animal on addition of standard amounts of PGI₂ and the same preparation of labelled

platelets. Assays were performed on fresh arterial blood from 27 conscious rabbits (New Zealand White, 2.5-3.5 kg). The observed mean value for the formation of ³H-labelled cyclic AMP in labelled platelets added to the fresh blood was in each case diminished by antibody to 6-keto-PGF_{1a}, but this decrease was only statistically significant in 11 individual animals (P < 0.05, one-sided t-test), indicating that blood concentrations of PGI₂-like compounds were close to the limit of sensitivity of the method. Estimates of the mean arterial presumptive PGI2 were made using groups of animals and the values obtained after correction for dilution by anticoagulant were $0.050 \pm 0.007 \,\text{pmol ml}^{-1}$ in 17 male rabbits and $0.066 \pm 0.066 \pm 0.006 \,\text{m}$ $0.017 \text{ pmol ml}^{-1}$ in 10 female rabbits (means \pm s.e.m.). Both mean values are significantly different from zero (P < 0.001 and <0.0025, respectively, in one-sided t-tests), but no significant difference between the sexes was detected. As addition of antibody did not decrease the cyclic AMP formed when labelled platelets were added to blood samples that had been preincubated at 37 °C for 30 min (P>0.1; t-test, n=6), the small but significant amount of PGI2-like material present before preincubation of these samples was probably PGI₂.

We have also assaved the PGI₂-like compounds in rabbit arterial blood at various times after rapid intravenous injection of PGI₂ at 1 nmol per kg (Table 1). Approximately 90% of the injected PGI₂ had disappeared from the circulation after 2 min and 99% after 5 min. When arterial blood taken 2 min after injection of PGI₂ was incubated at 37 °C (see Fig. 2), the assayable activity disappeared with a half life of 8.3 ± 0.3 min (mean \pm s.e.m., n = 3), indicating the presence of PGI₂ rather than 6-keto-PGE, in the circulation. Intravenous injection of angiotensin II has been shown to lead to the appearance of a circulating PGI₂-like substance in both cats²⁰ and dogs^{21,22}. We have observed the same phenomenon in rabbits; 2 min after injection of angiotensin II at 5 nmol per kg, the arterial concentration of presumptive PGI₂ reached 7.55 ± 0.37 pmol ml⁻¹ and then declined rapidly (Table 1). The in vitro half life of the material present in the circulation after 2 min was 7.4 ± 0.5 min (mean \pm s.e.m., n = 3), indicating that it was probably PGI₂ and certainly not 6-keto-PGE1.

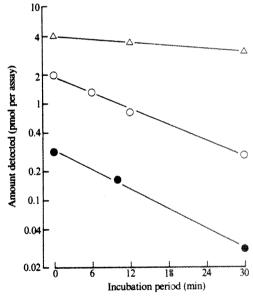

Fig. 2 Stability of PGI₂ and of 6-keto-PGE₁ in rabbit blood. Samples (0.4 ml) of citrated blood (pH 7.7) that had been preincubated for 60 min at 37 °C were mixed with 2 pmol of PGI₂ or 5 pmol of 6-keto-PGE₁. After further incubation at 37 °C for the indicated periods, IBMX and labelled platelets were added and the increase in platelet ³H-labelled cyclic AMP measured over 0.5 min. The PGI₂ or 6-keto-PGE₁ remaining was calculated from the effects of standard amounts of these prostaglandins added to samples of the same blood 0.1 min before the labelled platelets (see Fig. 1a). Samples of freshly drawn arterial blood from a rabbit injected 2 min previously with PGI₂ at 1 nmol per kg were assayed for PGI₂-like activity immediately and after incubation at 37 °C for 10 and 30 min. The decay of PGI₂ (O), 6-keto-PGE₁ (△) and of the PGI₂-like activity present in blood after injection of PGI₂ (●) are plotted on a semi-logarithmic scale.

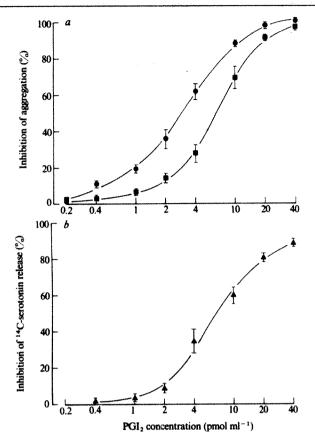

Fig. 3 Inhibition of rabbit platelet function by PGI₂. a, ADP-induced platelet aggregation. Incubation mixtures (1 ml) comprising 0.85 ml of citrated plasma containing 4.25×10⁸ platelets and PGI₂ at the concentrations indicated were stirred for 0.5 min at 37 °C in an aggregometer (Payton Associates) before addition of ADP. The per cent inhibitions by PGI₂ of the decreases in absorbance caused by 0.75 µM ADP (●) and 2 µM ADP (\blacksquare) after stirring for a further 0.5 min are shown (means \pm s.e.m., n = 5and 6, respectively). Control decreases in absorbance (means ±s.e.m.) were 0.134 ± 0.015 with 0.75 μ M ADP and 0.208 ± 0.019 with 2 μ M ADP. b, Collagen-induced release of serotonin. Incubation mixtures (1 ml) comprising 0.8 ml of citrated plasma containing 4 × 108 platelets (labelled by preincubation with 0.5 µM 14C-serotonin and the indicated concentrations of PGI₂ were stirred for 0.5 min before addition of collagen (50 µg ml⁻¹). After stirring for a further 2 min, 0.2 ml of 9% (w/v) paraformaldehyde was added, the samples were centrifuged and the release of platelet tonin into the supernatant was measured; this amounted to $57 \pm 5\%$ in controls without PGI_2 (n = 6). The per cent inhibitions of release (means ±s.e.m.) are shown (A).

To determine whether the small amounts of PGI₂ normally found in rabbit arterial blood could affect platelet function, we studied the sensitivity of the aggregation of platelets by ADP and of the release of platelet serotonin by collagen to inhibition by PGI₂ in rabbit citrated platelet-rich plasma (Fig. 3). As preliminary experiments showed that preincubation with PGI₂ for 0.5 min gave an optimal inhibition, this period was used subsequently. With a concentration of ADP that caused maximum aggregation (2 μM), an IC₅₀ for PGI₂ of 7 pmol ml⁻¹ was obtained (Fig. 3a), similar to the value reported by Whittle et al.²³. Almost the same concentrations of PGI₂ were required to inhibit the release of serotonin by collagen at 50 µg ml⁻¹ (Fig. 3b). With sub-optimal doses of ADP, PGI₂ was more effective (Fig. 3a), as expected in view of the ability of ADP to inhibit platelet adenylate cyclase⁵. However, no inhibition was observed with PGI₂ concentrations < 0.4 pmol ml⁻¹. 6-Keto-PGE₁ was approximately one-fifth as effective as PGI2 in inhibiting ADP-induced platelet aggregation.

Our experiments show that rabbit arterial blood contains trace amounts of a compound that shares three properties with PGI₂, namely the capacity to activate platelet adenylate cyclase, an affinity for an antibody to 6-keto-PGF1a and lability in whole blood. However, the values we have obtained for this presumptive PGI2 are one to two orders of magnitude lower than those implied by the collagen strip superfusion technique or by two studies in which 6-keto-PGF_{1a} levels were measured in rabbit serum¹² and plasma¹⁴. Although the collagen strip method did not allow accurate quantitation of circulating PGI2, antibody to PGI₂ enhanced the deposition of platelets from rabbit arterial blood to about the same extent as infusion of PGI₂ at 1 ng ml⁻¹ (2.8 pmol ml⁻¹) into venous blood depressed platelet deposition7. This suggests that arterial PGI2 concentrations of this order were present. A possible explanation of the discrepancy between these results and ours is that various features of the superfusion technique may stimulate PGI₂ synthesis, for example, the embolization of platelet aggregates from the collagen strip into the lungs. Intravenous injection of an air embolus has been shown to stimulate the release of PGI₂ in the cat⁸. The high 6-keto-PGF_{1a} content of rabbit serum¹² may reflect synthesis of PGI₂ by white cells from PGH₂ released by stimulated platelets²⁴. Although one group¹⁴ has reported a mean 6-keto-PGF_{1 α} concentration of 0.75 ng ml⁻¹ (2 pmol ml⁻¹) in rabbit plasma, another group¹⁵ obtained values for plasma 6-keto- $PGF_{1\alpha}$ of less than 0.1 ng ml⁻¹ (0.3 pmol ml⁻¹).

We believe our technique provides the most sensitive and accurate method yet available for measuring blood PGI2. The results obtained show that in physiologically normal rabbits, the arterial concentration of PGI2 is an order of magnitude too low to affect platelet function. Thus, our findings do not support the concept, based partly on experiments with rabbits⁷, that PGI₂ is a circulating hormone that regulates platelet aggregability course, the absence of significant PGI₂ from the normal circulation does not preclude its release in large amounts and distant action in conditions that provoke its synthesis by a substantial fraction of the pulmonary or peripheral vascular bed, as is apparently observed after injection of angiotensin II. However, in view of the fairly rapid clearance of PGI₂ from the circulation that we and others²⁵ have observed, we suggest that the synthesis and action of PGI2 are most often likely to be part of a local response to a local stimulus. Such PGI₂ synthesis may have important functions in limiting the extension of haemostatic plugs and thrombi²⁶⁻²⁹ and in the dispersal of platelet aggregates trapped by the lungs and other organs³⁰

We thank Dr J. B. Smith of Thomas Jefferson University, Philadelphia, and Dr M. A. Blaichman of McMaster University, Hamilton, for providing antisera to 6-keto-PGF₁₀, Dr J. F. Mustard of McMaster University for supplying apyrase and Dr J. Pike of Upjohn Co. for samples of PGI₂, 6-keto-PGE₁ and 6-keto-PGF_{1a}. This work was supported by a grant from the Ontario Heart Foundation.

The phosphatidylinositol cycle and the regulation of arachidonic acid production

Eduardo G. Lapetina, M. M. Billah & P. Cuatrecasas

Department of Molecular Biology, The Wellcome Research Laboratories, Research Triangle Park, North Carolina 27709, USA

An increase in the metabolism of phosphatidylinositol occurs in a wide variety of tissues by the action of specific ligands¹⁻³. In platelets, the interaction of thrombin with its receptor initiates the degradation of phosphatidylinositol by the action of a specific phospholipase C (refs 4-8). In normal conditions of stimulation, the resultant 1,2-diacylglycerol is rapidly and completely phosphorylated to phosphatidic acid⁴⁻¹¹. The formation of phosphatidic acid precedes the release of arachidonic acid from the phospholipids of stimulated platelets5. This early appearence of phosphatidate might result in the initial production of arachidonic acid and lysophosphatidic acid by the action of a phospholipase A2 specific for phosphatidate12 Phosphatidate/lysophosphatidate could induce calciumgating 13-15 and subsequently stimulate phospholipases of the A2-type8, that degrade phosphatidylcholine, phosphatidylethanolamine and a further fraction of phosphatidylinositol6. Alternatively, the lysophosphatidate produced may serve as a substrate for the transfer of arachidonate directly from other phospholipids 16,17 to form new phosphatidate which in turn can release more arachidonate. Overall, such a sequence would be equivalent to phospholipase A2 activation of other phospholipids. Our present data indicate that when the release of arachidonic acid is completely inhibited by cyclic AMP or quinacrine, phosphatidic acid is redirected entirely to phosphatidylinositol and there is no production of arachidonate. In these conditions, the availability of calcium might be profoundly restricted. The correlation in platelets of a phosphatidylinositol by a specific phospholipase A2 might suggest that these phenomena are applicable to activations in other cell systems.

Phosphatidylinositol is not the only phospholipid that contributes to the production of arachidonic acid in stimulated platelets^{4-10,18}. Phosphatidylcholine and phosphatidylethanolamine also release arachidonic acid by the action of phospholipase A2 activities8. Both lysophosphatidylcholine and lysophosphatidylethanolamine have recently been found in stimulated platelets 10,18. In a similar way, lysophosphatidic acid is also produced in intact platelets that have been prelabelled with ³²P and stimulated with thrombin (Fig. 1). Thrombin is very effective in producing phosphatidic acid^{4-6,19} and lysophosphatidic acid¹⁹, whereas ionophore A23187 forms virtually no phosphatidic acid^{4,5} or lysophosphatidic acid (Fig. 1). Calcium ions enhance the thrombin-induced formation of phosphatidic acid as well as of lysophosphatidic acid (Fig. 1). We have described elsewhere the existence of a specific phospholipase A₂ which is present in platelet membranes and which specifically degrades phosphatidic acid¹². This enzyme activity $(K_m 20 \mu M)$ is most active at pH 7.0, requires Ca²⁺ (10 μM) for maximal activity and is inhibited by quinacrine¹². The existence and specific properties of this enzyme suggest a possible important role in the production of arachidonic acid in stimulated platelets. This phosphatidate-specific phospholipase A₂ has distinctly different properties from those of the phospholipases A2 that degrade phosphatidylethanolamine and phosphatidylcholine8, as its activity does not depend on the presence of detergents, alkaline pH or high concentration of Ca

Phosphatidate is a key intermediate in the phosphatidylinositol cycle¹⁻³. In this cycle, four consecutive enzyme activities are involved in the degradation and resynthesis of phosphatidylinositol (phosphatidylinositol-specific phospholipase C; 1,2-diacylglycerol kinase; CTP-phosphatidate: cytidyl

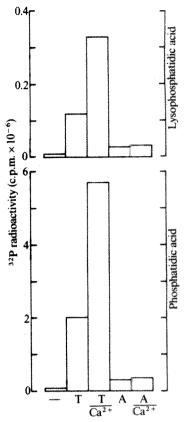

Fig. 1 Effect of thrombin and ionophore A23187 on the formation of phosphatidic acid and lyosphosphatidic acid in platelets. Horse platelets were labelled with ³²P-orthophosphate after separation from one (550 ml) unit of bibod as described previously^{5,6}. Platelets were then resuspended in 10 ml of buffer (134 mM NaCl, 15 mM Tris-HCl pH 7.4, 1 mM EGTA, 5 mM glucose), 5 mCi of ³²P-orthophosphate were added and the platelets incubated at 37 °C for 2 h. After centrifugation and resuspension, the final concentration of platelets was 1×10⁹ per 0.5 ml, which was the volume used for the assays. Samples (0.5 ml) were incubated with thrombin (T) (1 unit ml⁻¹)-or ionophore A23187 (A) (1 μM) ± calcium chloride (3 mM) in both cases, for 10 min at 37 °C. Lipid extraction and chromatographic separation of lipids have been detailed elsewhere^{5,6}. Phosphatidic acid and lysophosphatidic acid were separated by a TLC method which uses oxalate-impregnated plates as described before¹².

phosphatidyl CDP-1,2-diacylglycerol-inositol transferase: transferase). To study the effects of calcium on the phosphatidic acid and phosphatidylinositol of stimulated platelets, platelets were labelled with 32P-orthophosphate and resuspended in an EGTA-containing buffer. If those platelets are then incubated with quinacrine and stimulated with thrombin, the release of arachidonic acid is completely blocked but phosphatidic acid is formed as a consequence of the degradation of phosphatidylinositol⁶. After an initial period, the label in phosphatidate decreases while the labelling of phosphatidylinositol increases (Fig. 2). This increased conversion of phosphatidate to phosphatidylinositol is blocked by the addition of ionophore A23187 plus calcium ions (Fig. 2). In this case, there is a further accumulation of labelled phosphatidic acid while the increased labelling of phosphatidylinositol is completely blocked (Fig. 2). These results indicate that calcium inhibits the resynthesis of phosphatidylinositol from phosphatidic acid after thrombin stimulation (Fig. 2)¹⁰. In fact, Ca²⁺ has a direct inhibitory action on the enzymes involved in the resynthesis process (CTPphosphatidate: cytidyl transferase and CDP-1,2-diacylglycerolinositol phosphatidyl transferase)20,21 These data indicate that the phosphatidylinositol cycle can actively function in the presence of quinacrine, which completely blocks the production of arachidonic acid from all platelet phospholipids⁶. Calcium, on the other hand, interrupts the phosphatidylinositol cycle and phosphatidate accumulates (Fig. 2).

Cyclic AMP inhibits the 'release reaction' of platelets as well as aggregation⁴. The action of cyclic AMP on platelet enzymes has been variously ascribed to the inhibition of the conversion of arachidonic acid to cyclooxygenase metabolites²², the production of arachidonic acid from phospholipids^{4,23-27} and the formation of phosphatidic acid^{4,5}. All these actions ultimately reduce the production of arachidonate or its conversion to active cyclooxygenase products. We previously described the action of cyclic AMP in reducing phosphatidic acid to an inhibition of phospholipase C7. Further studies now reveal that the phosphatidylinositol cycle is not inhibited by cyclic AMP despite the profound reduction in the quantity of phosphatidate produced. Figure 3 describes the action of cyclic AMP on the reactions related to the increased turnover of phosphatidylinositol in platelets prelabelled with ³²P-orthophosphate. Cyclic AMP seems substantially to increase the rate of conversion of phosphatidate to phosphatidylinositol, thereby decreasing the steady state concentration of phosphatidate. As we are proposing that the production of arachidonic acid might be related to the formation of phosphatidate, this could serve as the basis for the cyclic AMP-induced inhibition of arachidonate production. In the presence of quinacrine, which completely blocks the formation of arachidonic acid from various phospholipids^{6,12}, thrombin greatly increases the breakdown and resynthesis (turnover) of phosphatidylinositol as shown by increased labelling of ³²Pphosphatidylinositol (Fig. 3). These data indicate that the integrity of the phosphatidylinositol cycle is maintained in

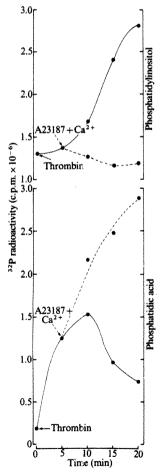

Fig. 2 Effect of ionophore A23187 plus calcium ions on phosphatidylinositol and phosphatidic acid of platelets pretreated with quinacrine and thrombin. Platelets prelabelled with ³²P-orthophosphate were obtained as for Fig. 1. Samples (0.5 ml) were incubated with quinacrine for 5 min at 37 °C and then thrombin (1 unit ml⁻¹) was added for different periods of time as indicated. After 5 min treatment with thrombin, in some assays (----) ionophore A23187 (1 µM) plus calcium chloride (3 mM) were added. Other details as for Fig 1.

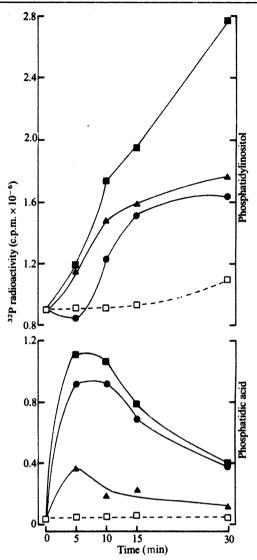

Fig. 3 Effect of thrombin on phosphatidylinositol and phosphatidic acid of platelets pretreated with cyclic AMP or quinacrine. Preincubations with quinacrine (0.75 mM) (or dibutyryl cyclic AMP (1 mM) (A) were for 5 min and thrombin (1 unit ml⁻¹) was then added for different periods of time as indicated. . Assays containing only thrombin; , control assays. Phosphatidic acid was separated on TLC⁵ and phosphatidylinositol was separated on formaldehyde-impregnated paper^{5,6}. Other details as for Fig 1.

conditions (cyclic AMP or quinacrine) in which the specific release of arachidonic acid induced by thrombin is completely blocked.

The information presented here indicates that calcium interrupts the phosphatidylinositol cycle¹⁻³ and leads to accumulation of the intermediate product, phosphatidic acid. In stimulated platelets a specific phospholipase A₂ released arachidonic acid from the phosphatidate produced¹², with the consequent appearence of lysophosphatidic acid. This phosphatidate-lysophosphatidate interconversion might important in the subsequent and specific mobilization of phosphatidylcholine, arachidonic acid from phatidylethanolamine and phosphatidylinositol⁶. In thrombinstimulated platelets cyclic AMP enhances the overall turnover of the phosphatidylinositol cycle by increasing the rate of conversion of phosphatidic acid to phosphatidylinositol, and thus inhibits the release of arachidonic acid from various phospholipids.

4',6-Dichloroflavan (BW683C), a new anti-rhinovirus compound

D. J. Bauer, J. W. T. Selway*, J. F. Batchelor, Margaret Tisdale, Ian C. Caldwell & D. A. B. Young

Wellcome Research Laboratories, Langley Court, Beckenham, Kent BR3 3BS, UK

Derivatives of flavan have been synthesized as chemical intermediates, but the only reported biological action is the ability of certain alkyl and alkoxy derivatives to lower blood cholesterol concentrations1. It was therefore surprising to discover that flavan itself (Table 1) is a highly effective inhibitor of the replication of certain serotypes of rhinovirus, and that a simple derivative, BW683C (4',6-dichloroflavan), is the most potent antiviral compound yet reported. The present work examines the antiviral activity of flavan derivatives with a view to selecting the compound most suitable for trial in volunteers infected with a common cold virus.

4',6-Dichloroflavan, which is new to the chemical literature, has been prepared by methods used for the synthesis of substituted flavans²⁻⁵. It is a colourless crystalline solid, m.p. 101 °C, soluble in water only to the extent of 1 mg l⁻¹ at room tempera-

Antiviral activity was detected in vitro by means of plaque inhibition tests^{6,7} with monolayers of M-HeLa cells^{8,9} infected with rhinovirus 1B. Activity was measured by plaque reduction assays in which doubling concentrations of compound were incorporated into the overlay medium. Plaque counts, expressed as a percentage of the control value, were plotted against the logarithm of the compound concentration, to yield a doseresponse line from which the IC₅₀ value could be determined. The IC₅₀ values for BW683C and several analogues are shown in Table 1. Flavan ($R_6 = R_{4'} = H$), with an IC₅₀ of 0.046 μ M, is one of the least active of the compounds tested. The activity is generally increased by the presence of a single halogen substituent, and more so by the presence of two chlorine atoms, with the most active compound tested being BW683C which, with an IC_{50} of 0.007 μ M, is some six times more potent than the parent compound. The IC90 of BW683C was $0.02~\mu M$.

Structure-activity relationship of a selection of halogen-Table 1 substituted flavans against rhinovirus type 1B

For any agent to be effective in the prophylaxis or treatment of the common cold, it must be active against a high proportion of rhinovirus serotypes. There are at least 89 serotypes, the most prevalent being 1A, 1B, 2, 4, 15, 29, 30 and 31 (ref. 10). IC₅₀ values were obtained for BW683C against 19 serotypes (Table 2). Seven of the eight most prevalent serotypes were inhibited, although they varied considerably in sensitivity. The sensitivity of the other 11 serotypes was also variable, but was sufficient to suggest that the compound may be clinically useful.

In tissue culture tests 4',6-dichloroflavan did not inhibit the replication of other RNA viruses, including bunyavirus, coronavirus, equine rhinovirus, influenza virus (NWS strain), measles virus, poliovirus (Sabin 1), Semliki Forest virus, Sindbis virus and respiratory syncytial virus. It also failed to inhibit the DNA viruses adenovirus type 5 and herpesvirus type 1.

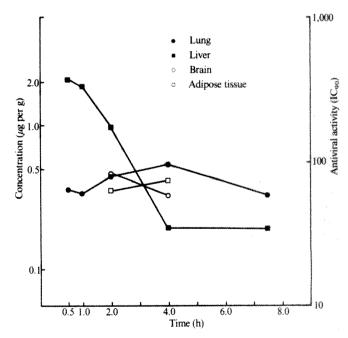

Fig. 1 Tissue concentrations of BW683C determined by gasliquid chromatography. Tissue homogenate (1 ml) was mixed with 0.5 ml ethylene glycol/water/2 M citric acid (2:2:1) and 5 ml hexane. The mixture was shaken for 30 min and centrifuged. The hexane layer was collected and mixed with 1 ml of a mixture of ethylene glycol/1 M Na₂CO₃ (1:9), shaken again and centrifuged. The upper layer was collected, dried in a stream of N₂ and the residue was dissolved in a small volume of toluene

^{*} Serotypes described by Roebuck¹⁰ as common.

Preliminary studies were carried out on the absorption and tissue distribution of 4',6-dichloroflavan in rats after its administration at 5 mg per kg by gavage as a suspension of finely ground particles in aqueous methylcellulose. Samples of plasma and selected tissues were collected at intervals up to 7.5 h after dosing, and unchanged compound was determined by analysis of tissue extracts by gas-liquid chromatography with electron capture detection or by specific ion monitoring using a mass spectrometer. Highest concentrations were found in liver (Fig. 1); peak concentrations of $\sim 7.3 \, \mu M$, some 350 times the IC₉₀, were observed at 0.5 h, and these declined rapidly. Concentrations of compound well in excess of the IC₉₀ value were also detected in plasma, lung, brain and adipose tissue, and the time of peak compound concentrations in lung samples seemed to occur between 2 and 4 h after dosing; compound concentrations in excess of the IC₉₀ level could still be found in lung 7.5 h after dosing. These results indicate that 4',6-dichloroflavan is adequately absorbed from the gastrointestinal tract, and that compound concentrations well above those required for maximum antiviral activity in vitro can be attained at doses as low as 5 mg per kg. The apparent persistence of this compound implies that infrequent administration may suffice to maintain effective antiviral concentrations in vivo. The above findings were supported by autoradiography of rats, which received 'H-BW683C as an aqueous suspension by gavage, and were killed 2 or 4 h later.

When BW683C was added to HeLa cells in culture no cytotoxic effects were observed at drug concentrations up to 3.6 µM, the limit of aqueous solubility and many times the IC₉₀ and IC₅₀ values determined with rhinovirus 1B. In the rat, the LD₅₀ after subcutaneous administration was ~300 mg per kg; animals showed no ill effects after oral administration at doses up to 1 g per kg or intraperitoneal administration at doses up to 700 mg per kg. BW683C showed no evidence of mutagenicity when tested in the presence or absence of a liver microsome preparation by the method of Ames¹¹

Preliminary studies showed that BW683C interacted directly with virus, reducing infectivity by about 0.5 log unit, but it was not a typical contact inactivator because inactivation did not increase with time. The possible binding of compound to virus particles was investigated by mixing tritiated compound with virus and centrifuging the mixture through a 15-45% sucrose gradient; radioactively labelled compound was found in the virus peak.

In a time-of-addition study, the compound was added at hourly intervals throughout a single growth cycle of rhinovirus 1B in M-HeLa cells. Maximum antiviral activity was obtained when the compound was added to the culture at the same time as the virus. Although some antiviral activity was observed when addition was delayed for 1 h or longer, it was no greater than that obtained by adding compound at the end of the cycle.

Further experiments with ³H-uridine-labelled virus indicated that the compound does not interfere with adsorption of the virus to the cell, nor with the uncoating or entry of the viral RNA into the cell. However, viral RNA synthesis was inhibited by the presence of the compound. BW683C therefore seems to bind to the virus and to inhibit some stage of viral replication immediately following entry of the viral RNA into the cell.

We thank Mr C. J. Bradley for technical assistance, Mr D. Farebrother for the autoradiography and Dr W. B. Moore for performing the Ames test.

Mutation of gene encoding regulatory polypeptide of aspartate carbamoyltransferase

André Feller*†, André Piérard*†, Nicolas Glansdorff†‡, Daniel Charlier†‡ & Mariolène Crabeel†‡

In our studies on the regulation of the expression of the genes for the biosynthesis of arginine and pyrimidines in Escherichia coli, we discovered that an aspartate carbamoyltransferase (ATCase) synthesized in vitro from our λ transducing phage λ0TC3 lacked substrate cooperative interactions and was insensitive to feedback inhibition by CTP. We show here that these abnormal properties result from a mutation in the gene for the regulatory polypeptide chain of ATCase. We believe this to be the first report of a mutation in the gene for this regulatory

ATCase catalyses the first reaction specific to pyrimidine biosynthesis, the formation of N-carbamoyl-L-aspartate from L-aspartate and carbamoylphosphate. In E. coli, ATCase activity is modulated by feedback inhibition by CTP, the end product of the pyrimidine pathway, and activation by ATP, product of the parallel purine pathway¹. Because E. coli ATCase exhibits the various types of regulatory interactions characteristic of allosteric proteins, it has been considered a model system and has become the most extensively investigated regulatory enzyme^{2,3}. It differs, however, from most other allosteric proteins in that its catalytic and regulatory functions can be physically separated. Native ATCase, with a molecular weight (MW) of 300,000, consists of two trimeric subunits which possess catalytic activity but are insensitive to the allosteric effectors and three dimeric subunits which are catalytically inactive but bear the effector binding sites⁴⁻⁶. Thus, the completely different catalytic (C) and regulatory (R) chains (respective MWs 34,000 and 17,000) form a 2C₃: 3R₂ structure. Zn²⁺ ions, one per regulatory chain, are required to stabilize this quaternary structure7

The zinc-binding domains on the regulatory subunits participate in the R:C bonding domains essential for the allosteric interactions¹⁰. The gene pyrB coding for the catalytic chain of ATCase lies at 96 min on the $E.\ coli$ chromosome ^{11,12}, but the localization of the gene for the regulatory chain has been hampered by the failure to obtain mutations affecting this gene. However, a thorough investigation of their biosynthesis 13,14

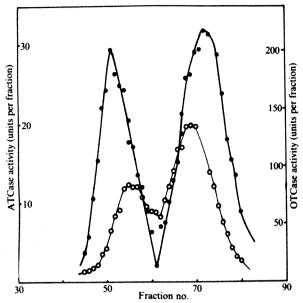

Fig. 1 Analysis of aspartate carbamovltransferase (ATCase) from strain PR7 by gel filtration on a column of Sephadex G-200. A 1-ml sample (containing 1,200 units and 10 mg protein) of crude extract of PR7 cells grown on minimal medium and extracted as described previously 21.22 was filtered on a 2.5 × 40-cm column of Sephadex G-200 equilibrated with 50 mM potassium phosphate buffer (pH 7.5). Elution was performed using the same buffer and 1.5-ml fractions were collected. E. coli and Streptococcus faecalis ornithine carbamoyltransferase (OTCase), exhibiting respective apparent MWs of 140,000 and 250,000 (ref. 23), were used as protein markers for calculating ATCase molecular weight. ATCase activity was determined by measuring the formation of ¹⁴C-carbamoylaspartate from ¹⁴C-carbamoylphosphate. The complete $(600 \,\mu 1)$ assay mixture containing 50 mM Tris-acetate (pH 8.0), 20 mM L-aspartate, 5 mM 14 C-carbamoylphosphate $((0.03 \,\mathrm{mCi \,mmol^{-1}})$ and enzyme sample was incubated at 37 °C for 15 min. The reaction was stopped by the addition of 400 $\mu l\,0.25~M$ trichloracetic acid. After 5 min boiling to destroy the non-reacted carbamoylphosphate, ¹⁴CO₂ formed was eliminated by bubbling air for 5 min. A 0.5-ml sample was counted in a model LS-100 Beckman liquid scintillation spectrometer in the presence of a scintillation cocktail containing 4 parts of Triton X-100 to 6 parts of a solution containing 0.5% 2,5-diphenyloxazole and 10%naphthalene in dioxane. A blank obtained by omitting the enzyme sample was subtracted from the results. OTCase was assayed as described previously²⁴. Units of enzyme activity are µmol of product formed per h. O, ATCase activity; O, OTCase activity.

suggested the existence of an operon encoding both types of ATCase chains in the order catalytic first and regulatory next. Moreover, in Salmonella typhimurium, which has a very similar ATCase¹⁵, pyrB deletions have been found to produce no detectable regulatory subunit¹⁶. The present study characterizes a λ transducing phage carrying the genetic determinants of an E. coli ATCase with modified regulatory subunits. This establishes the proximity of the genes encoding both types of chain. In agreement with this conclusion, the pyrB region of E. coli was

cloned recently as a 2,800-base pair DNA fragment encoding both subunits of ATCase (J. R. Wild & G. A. O'Donovan, personal communication). In agreement with Wild et al. (see accompanying report)¹⁷ in the present study we reserve the designation pyrB for the gene encoding the C chain of ATCase and use the symbol pyrI for the R chain of this enzyme.

 λ Bacteriophages transducing the contiguous *E. coli* genes argI (encoding ornithine carbamoyltransferase) and $pyrB^{18}$ have been used as a source of template DNA for in vitro synthesis of ATCase¹⁹. However, the enzyme synthesized using one of these DNA sources, λ 0TC3, was insensitive to CTP inhibition and exhibited hyperbolic aspartate saturation curves. Accordingly, bacteriophage λ 0TC3 was introduced into strain KMBL1510 G4, a thermoresistant derivative of strain KMBL1510 (F⁻ pyrB::Mu-1 cts62) that produces no detectable amount of either ATCase subunit (G. Hervé and B. Perbal, personal communication).

ATCase activity in the resulting strain PR7, was only slightly sensitive to CTP and lacked cooperative interactions with aspartate. When cell extracts of strain PR7 were submitted to gel filtration on a column of Sephadex G-200 (Fig. 1), two ATCases were observed with respective MWs of 300,000 and 100,000. Using the same experimental conditions, practically all the ATCase activity of a wild-type strain for this enzyme was present as a single activity peak with a MW of 300,000, and negligible amounts as the 100,000 MW species. Both ATCase forms of strain PR7 exhibited hyperbolic aspartate saturation curves (Fig. 2b, c), the half-saturation concentration of the larger form ($[S]_{0.5} = 6.5 \text{ mM}$) being significantly lower than that of the smaller form ($[S]_{0.5} = 23 \text{ mM}$). Whereas the larger ATCase of strain PR7 exhibited a reduced response to CTP and ATP, the smaller ATCase of this strain was totally insensitive to these effectors.

Comparison of the two ATCases of PR7 with the wild-type holoenzyme and its catalytic subunit (Table 1) suggested that the smaller ATCase (trimeric C₃) was identical with the wild-type catalytic subunit. The larger species corresponded to a 300,000-MW holoenzyme formed from this same catalytic subunit associated with a modified regulatory subunit. This interpretation is supported by the following experiments. (1) Treatment of the larger ATCase from PR7 with p-hydroxymercuribenzoate20 vielded a smaller ATCase (MW 100,000) having all the properties of the wild-type catalytic subunit. (2) A single ATCase species (MW 300,000) displaying sigmoidal aspartate saturation and effector responses similar to those of wild-type ATCase (Table 1 and Fig. 2a, d) could be reconstituted by combining the catalytic trimer of strain PR7 with purified wild-type regulatory subunit. (3) A similar reconstitution could be achieved in vivo by introducing the phage λ 0TC3 into strain 30S0U4 Hfr thi pyrB) harbouring a missense mutation in the pyrB gene but producing normal regulatory chain (Fig. 2e). These results indicate that phage λ 0TC3 encodes a wild-type catalytic ATCase chain and a modified regulatory chain.

The precise nature of the modification affecting the regulatory chains of ATCase remains to be determined. Nevertheless, heteroduplex analysis (not shown) of phage $\lambda 0 \text{TC}3$ indicates

Table 1 Comparison of aspartate carbamoyltransferases (ATCases) used in the present study

that the modified gene lies at the extremity of a 7,300-base pair chromosomal segment inserted into the phage genome. It is therefore possible that a short 3'-terminal portion of the gene has been deleted during the formation of phage λ 0TC3. This hypothesis is being evaluated by cloning and sequencing the modified regulatory gene. Interestingly, the C-terminal end of the regulatory chain with its zinc-binding sites lies at the interface between the regulatory and catalytic chains 10. Even short 3'-terminal deletions affecting the regulatory chain may thus impair the R: C binding domain. This might be the case for the modified ATCase encoded by \(\lambda\) OTC3 which, as suggested by the presence of two ATCase forms in extracts of strain PR7, may be impaired in holoenzyme assembly.

[Aspartate] (mM)

Further work is being done on the purification and characterization of the heavy ATCase species encoded by λ 0TC3. A detailed analysis of this unusual enzyme and its comparison with the wild-type enzyme may be vital for determining the role of the R:C domain of bonding in the allosteric interactions of ATCase. For example, it will be of interest to investigate whether the modified regulatory subunits have altered proper-

Fig. 2 Aspartate saturation curves of various aspartate carbamoyltransferase (ATCase) species analysed here. a, ATCase from wild-type strain P4X (Hfr P4X metB); b, holo ATCase peak of strain PR7; c, catalytic ATCase peak of strain PR7; d, ATCase reconstituted from the catalytic subunit of ATCase of PR7 and wild-type regulatory subunits; e, ATCase of the strain obtained by introducing the phage $\lambda 0TC3$ into strain 30S0U4 (Hfr thi pyrB) harbouring a missense mutation in the pyrB gene but producing normal regulatory chains. Reconstruction was achieved by mixing equimolar amounts of the two kinds of subunits in the presence of 0.2 mM zinc acetate, 10 mM 2-mercaptoethanol and 50 mM K-phosphate (pH 7.5) as described by Cohlberg et al.9. After incubation for 30 min at 37 °C, the mixture was filtered on Sephadex G-200 as in Fig. 1 and the newly formed 300,000-MW ATCase peak was collected and analysed. All ATCase assay conditions were as for Fig. 1. Relative activities are normalized to the activity measured without effector in the presence of 50 mM aspartate. In the absence of allosteric effector; O, in the presence of 5 mM ATP; ∇ , in the presence of 2 mM CTP.

ties towards zinc. Although the ATCase distribution shown in Fig. 1 could not be modified following growth in the presence of high Zn²⁺ concentrations, preliminary experiments suggest that reaggregation of the two kinds of subunits of strain PR7 can be promoted in vitro provided that a high enough Zn2+ concentration is present.

We thank Dr Guy Hervé for the gift of pure native ATCase subunits, and Drs Guy Hervé, Bernard Perbal, Gerard A. O'Donovan and James R. Wild for helpful discussions and suggestions. This work was supported by a grant of the Fonds de la Recherche Fondamentale Collective-Fonds voor Kollektieve Fundamenteel Onderzoek to A.P. and N.G.

A mutation in the catalytic cistron of aspartate carbamovltransferase affecting catalysis, regulatory response and holoenzyme assembly

James R. Wild, Karen F. Foltermann*. William D. Roof* & Gerard A. O'Donovan*

Genetics Section and *Department of Biochemistry and Biophysics, Texas A & M University, College Station, Texas 77843, USA

We describe here a mutation in the gene encoding the catalytic subunit of aspartate carbamoyltransferase (ATCase, pyrB) which produces an enzyme retaining catalytic activity as holoenzyme (2C₃:3R₂) and catalytic trimer (C₃) but which shows neither cooperative substrate kinetics nor nucleotide effector response. Furthermore, the holoenzyme assembly seems quite fragile in that the enzymatic activity is recovered only partially as holoenzyme following growth of Escherichia coli in the presence of zinc. In contrast, the enzyme from wild-type E. coli strain E63 is recovered almost entirely in its dodecameric form in identical conditions. The gene encoding the mutant pyrB was isolated from a AdargI+pyrB+ transducing phage (obtained from N. Glansdorff). This mutation differs from other previously reported mutations affecting the catalytic subunit^{1,2} in that significant catalytic activity is retained but homotropic and heterotropic communication is lost³.

A 6.0-kilobase fragment was isolated from purified λDNA^4 , restricted with the endonuclease PstI (Bethesda Research Laboratory)⁵, and cloned on to plasmid pBR322 (ref. 6). The recombinant plasmid pPB-h204 (plasmid-pyrimidine-B cistron-holoenzyme-strain 204) was transformed into E. coli WR38, which contains a Mu insertion in the chromosomal pyrB and does not produce catalytic or regulatory polypeptides as determined by immunoassay with specific antisera (W.D.R., unpublished observations). This plasmid encodes both the catalytic (pyrB) and the regulatory (pyrI) polypeptides of ATCase. [A mutation in the cistron encoding the regulatory polypeptide is described in the accompanying report by Feller et al. $^{\circ}$. The cistron is designated pyrI in agreement with Bachmann (personal communication).] The synthesis of ATCase in the transformed strain, WR38-h204, is repressed by growth in uracil, so that the cloned fragment contains the operatorpromoter region as well as both ATCase cistrons. The catalytic activity recovered from this strain is distributed as ~40% holoenzyme with a molecular weight (M_r) of 300,000 and 60% as the catalytic trimer with a M_r of 100,000. Both forms of ATCase from this mutant lack cooperative homotropic kinetics for aspartate, do not respond to the allosteric effectors ATP and CTP, and seem to have altered affinities for aspartate.

ATCase is the archetype of allosteric enzymes because: (1) both its substrates, carbamoyl phosphate and aspartate, produce

Table 1 ATCase holoenzymes from wild-type E. coll strain E63 and mutant E. coli strain WR38-h204

	Wild-type	Mutant
[S] _{0.5} (mM aspartate) % Activity + CTP % Activity + ATP	5.5 mM 21% 166%	2.0–2.5 mM 97% 105%
ATCase activity at pH 7.0 ATCase activity at pH 8.4	3.1	0.51
Shape of velocity-substrate curve	Sigmoidal	Hyperbolic

ATCase assay mixtures of 2.0 ml volume contained 40 mM potassium phosphate, pH 7.0, 3.6 mM dilithium carbamoyl phosphate, pH 7.0, 5 mM potassium aspartate, pH 7.0, for the wild-type and 2.5 mM for the mutant (approximate $[S]_0$ values), and enzyme (holoenzyme fractions of G-200 cluate, Fig. 2). CTP or ATP was absent from control tubes and present at a concentration of 2 mM when inhibition (CTP) or activation (ATP) was measured. The control activity, that is, the activity in the absence of effector, is set at 100%. ATCase activity was assayed by measuring the amount of carbamoyl aspartate formed in 30 min at 30 °C as previously described23. Carbamoyl aspartate production was determined at 466 nm. Specific activity is expressed as nmol carbamoyl aspartate formed per min per mg protein. Specific activity of ATCase was determined in conditions in which carbamoyl aspartate formation was proportional to extract concentration and time. The value obtained for the ratio of ATCase specific activity at pH 7.0/ATCase specific activity at pH 8.4 may be used as an index for the presence or absence of cooperativity between catalytic sites for aspartate binding according to the methods of Kerbiriou and Hervé¹¹. A ratio of <1.0 signifies the absence of cooperativity; one of ≥2.0 reflects cooperative homotropic interactions. Practions from beneath the holoenzyme peak (Fig. 2) were used to estimate this ratio.

positive homotropic interactions between catalytic sites as evidenced by the sigmoidal dependence of activity on substrate concentrations^{9,10}, (2) substrate binding is subject to positive heterotropic interactions between catalytic and regulatory sites in the presence of ATP and negative heterotropic interactions with CTP¹¹⁻¹⁴, and (3) the binding of CTP is subject to negative homotropic interactions between the regulatory sites12 Moreover, ATCase is unusual among allosterically regulated enzymes, in that, as with yeast phosphofructokinase 16 regulatory protein is distinct and can be physically dissociated from the catalytic subunit. The assembly of the enzyme is a cytoplasmic event17 which produces a dodecamer with six regulatory and six catalytic polypeptides (r₆c₆) associated as two separable catalytic trimers and three regulatory dimers 18,19. The holoenzyme may be reversibly dissociated by mild treatment with mercurials such as p-chloromercuribenzoate20 or neohydrin²¹. The catalytic subunit (c₃) is insensitive to allosteric effectors, possesses a half-saturation concentration ([S]_{0.5}) higher for aspartate than the holoenzyme (8-10 mM compared with 5 mM) and produces a V_{max} that is two- to fourfold higher. The separate regulatory subunit (r2) has no catalytic activity although ATP and CTP may still be bound²⁰. On reassociation of the holoenzyme after removal of the mercurial by zinc replacement dialysis in the presence of dithiothreitol, the original catalytic and regulatory properties of the native enzyme are re-established²²

ATCase was prepared from E. coli wild-type strain E63 and the transformed mutant strain WR38-h204 by the methods of Wild et al.23. Several pertinent properties of the wild-type and mutant ATCases are compared in Table 1. We must emphasize three points regarding these data. (1) The mutant ATCase is not subject to allosteric regulation by either ATP or CTP at subsaturating concentrations of aspartate (1-5 mM). Minimal effector response was observed when velocity-substrate plots were examined over the range of 0.5 mM to 50 mM aspartate (<5% variation throughout the range). As noted by Gerhart² effects are due only to the direct competition for any phosphatecontaining compound. (2) The apparent [S]05 for aspartate of the mutant enzyme is significantly lower (2.0-2.5 mM) than the wild-type requirements (5.5 mM). (3) The homotropic kinetic responses of the mutant enzyme are dramatically reduced or abolished in the mutant enzyme as shown by the lack of sigmoidal dependence of activity on aspartate concentration (Fig. 1) even when plotted according to Eadie-Hofstee²⁵ (see insert Fig. 1). Thus, there is no apparent cooperativity from 0.5 to 10 mM (20% to fivefold [S]0.5, respectively). In addition, the

ratio of ATCase activity at pH 7.0 and 8.4 may be used as an index of the presence or absence of homotropic interactions between catalytic sites as first described by Kerbiriou and Hervé¹¹. A ratio of <1.0 signifies the absence of cooperativity and is always found for the catalytic subunits alone, whereas a ratio of \geq 2.0 reflects cooperative homotropic interactions¹¹. We have verified these observations in similar experiments (K.F.F. unpublished observations). By this criterion, the ATCase from strain WR38-h204 seems to lack cooperativity.

Figure 2 shows an analysis of the M_r values of the ATCases from mutant and wild-type enzymes in the presence of zinc. A single large molecular weight form ($\sim 300,000$) was observed from the wild-type extract. In contrast, more than half of the enzymatic activity from the mutant extract was observed as a smaller component ($M_r \sim 100,000$) which corresponds to the wild-type catalytic trimer. We have shown previously that all native ATCase from the enteric bacteria grown in sufficient zinc ($20 \,\mu\text{M}$) studied thus far are recovered entirely as holoenzyme²³. Only when zinc becomes limiting or there is an assembly defect can the catalytic trimer be recovered from cell-free extracts.

The following evidence suggests that these differences are consequences of an altered catalytic subunit. (1) The catalytic trimer from the mutant enzyme shows increased affinity for aspartate compared with the catalytic trimer ([S]_{0.5} of 5 mM aspartate compared with 8-10 mM) of the wild-type enzyme. (2) The M_r values of the catalytic trimers are indistinguishable, but they form clearly different holoenzymes when reconstituted with wild-type regulatory dimers (Table 2). The holoenzyme

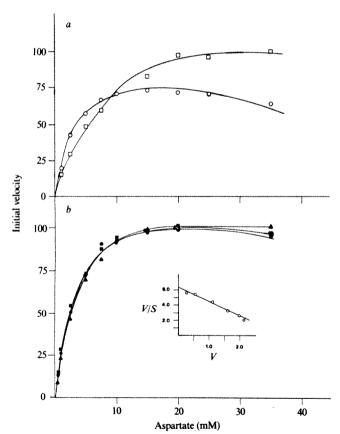

Fig. 1 Aspartate saturation curves for ATCase holoenzyme and its catalytic trimers from E. coli mutant strain WR38-h204. Enzyme samples were prepared as reported previously²³. Assay mixtures were as described in Table 1 legend except that the aspartate concentration was varied from 0.5 mM to 50 mM as indicated on the abscissa. CTP or ATP was absent from control tubes and present at 2 mM when inhibition (CTP) or activation (ATP) was measured. For the above comparisons initial rate values were normalized as described below. a, Velocity-substrate plots for aspartate of the ATCase holoenzyme (○) and its catalytic trimer (□) from the mutant. The maximum velocity for the catalytic trimers was set at 100 on the ordinate scale for convenience. b, Velocity-substrate plots for aspartate of the ATCase holoenzyme from the mutant in the absence of the effectors (●) and in their presence: CTP (△) or ATP (■).

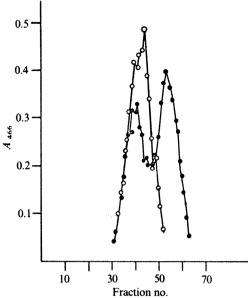

Fig. 2 Analysis of ATCase from E. coli wild-type E63 and mutant WR38-h204 by gel filtration on a G-200 Sephadex column; 1 ml, containing ~20 mg protein, of the appropriate cell-free extract was applied to the G-200 column, equilibrated previously with 40 mM potassium phosphate buffer pH 7.0, 0.1 mM dithiothreitol and 0.02 mM zinc acetate. The equilibration mixture was also used for elution. Individual fractions (abscissa) were assayed for ATCase by a spot assay. This differed from the usual assay²³ in that the final reaction volume was reduced from 2.0 ml to 0.2 ml and 30-50 mM aspartate was used. The ordinate gives absorbance at 466 nm, the wavelength for monitoring ATCase. A single wild-type peak (○) and two mutant peaks (●) are seen.

formed from wild-type regulatory dimers and mutant catalytic trimers has a M_r of $\sim 300,000$, but its regulatory and catalytic properties are those of the original mutant enzyme.

We have shown that a mutation in the pyrB gene, encoding the catalytic polypeptide of ATCase, can affect the homotropic and heterotropic interactions of the enzyme while maintaining catalytic activity. The reconstitution experiments with normal regulatory subunits purified from the native enzyme and catalytic subunits from both the mutant and wild-type strains prove that the catalytic polypeptide of the ATCase from strain WR38-h204 is altered. It is surprising that a mutation in the cistron encoding the catalytic polypeptide can affect such a wide range of enzymatic properties without completely disrupting the

Table 2 Catalytic trimers of ATCase from wild-type and mutant E. coli strains and their reconstituted holoenzyme derivatives

	Wild-type	Mutant
M_r for c_3	85,000-100,000	85,000-100,000
[S] _{0.5} aspartate for c ₃	8-10 mM	5 mM
M, for holoenzyme	280,000-300,000	280,000-300,000
[S] _{0.5} aspartate for		
holoenzyme	5.5 mM	2.0 mM
% Activity in 2 mM CTP	20	86-95
% Activity in 2 mM ATP	160	97-105

Reconstitution experiments were performed as follows. Catalytic subunits from the wild-type and mutant strains were mixed individually with excess of wild-type regulatory subunits and concentrated on an Amicon ultrafiltration system (PM-10 membrane) in the presence of 40 mM potassium phosphate buffer, pH 7.0, 0.2 mM zinc acetate, 2.0 mM dithiothreitol and 20 µM EDTA. The reconstitution of holoenzyme with both wild-type and mutant catalytic trimers was almost 100%. Effector response was measured exactly as described for Table 1. The effector response was determined at the appropriate [S]_{0.5} for each enzyme (that is 5 mM or 2.5 mM). Molecular weights were estimated using Sephadex G-200 ascending flow column chromatography. Standards used in column calibration were: RNase A, M_r 13,700; chymotrypsinogen A, 25,000; ovalbumin 45,000; aldolase 158,000; ATCase holoenzyme from E. coli 300,000; Blue Dextran 2000, 2×10^6 . These standard enzymes (5-20 mg of each, except ATCase) were prepared in a 2.0-ml volume of 40 mM potassium phosphate, pH 7.0, with 0.02 mM zinc acetate, 0.1 mM dithiothreitol, and applied to the column. The elution profiles of the various proteins were determined by monitoring absorbance at 280 nm. ATCase was used separately to verify the accuracy of the column at higher molecular weights. Catalytic and regulatory subunits from the wild type were prepared as described previously²¹. The catalytic subunit from the mutant was obtained from appropriate Sephadex G-200 column fractions (Fig. 2).

catalytic capabilities of the enzyme. This mutation should be compared with that affecting the regulatory polypeptide described by Feller et al. in the accompanying report. It is striking that the holoenzyme assembly is apparently deficient in both mutants, one affecting the catalytic sununit and the other the regulatory subunit.

. One final observation regarding the catalytic mutation seems pertinent. Examination of the kinetic characteristics (Fig. 1) of the mutant (with or without ATP added) revealed that they approximate the wild-type enzyme in the presence of ATP. Indeed, the high affinity exhibited by the mutant holoenzyme for aspartate suggests that the mutant ATCase may be frozen in its activated R state²⁶. The present data suggest that strikingly similar characteristics can exist for two independent mutations in either the catalytic or regulatory cistrons of ATCase.

Sequence dependence of the helical repeat of DNA in solution

Lawrence J. Peck & James C. Wang

Department of Biochemistry and Molecular Biology, Harvard University, Cambridge, Massachusetts 02138, USA

Considerable progress has recently been made on the fine structure of DNA. X-ray diffraction studies of crystals of oligonucleotides of defined sequences have already provided several structures at atomic resolution 1-6. Whereas all the crystals studied so far show bihelical structures with antiparallel chains and Watson-Crick-type base pairing, there is a striking range of structural variability, from the right-handed B-type to the left-handed Z-type helices. In contrast to the well developed methology for crystal structure determination, few methods of high precision and low ambiguity are available for studies of DNA in solution. Here we report the application of the bandshift method previously developed in this laboratory to the determination of the dependence of the DNA helical repeat in solution on its nucleotide sequence.

Fig. 1 Sequences of homopolymer tract inserts. Clones were initially acreened for insert size by following the restriction endonuclease Hae III digest on a 6% polyacrylamide gel. For DNA sequencing, the insert containing the Alul-generated restriction fragment was isolated, end-labelled, and sequenced after strand separation according to the procedures of Maxam and Gilbert²¹ most cases both strands were sequenced. No changes in plasmid sequence were observed outside the PstI site.

The principle of the band-shift method has been reported elsewhere. Note that the helical repeat, ho, obtained from the band-shift method is the number of base pairs of the sequence inserted that will increase the average linking number of the DNA in its relaxed state by one. In cases where the insert does not have an intrinsic spatial writhe, h^0 is also identical to the number of base pairs that forms a complete helical turn.

In addition to the absolute magnitudes of the helical repeats of different sequences, the band-shift method gives the relative handedness of the helices. We shall make the generally accepted assumption that a double-stranded DNA of typical sequence is a right-handed helix in solution. The band-shift method then provides directly the handedness of the inserted helical segments as well.

To extend the band-shift method to the determination of the helical repeats of DNAs of defined sequences, families of covalent closed circular DNAs containing inserts of these sequences of known lengths are needed. The method used to insert homopolymer tracts of various lengths into the PstI site of pBR322, a plasmid with known nucleotide sequence 10, involved tailing with terminal transferase and one of the deoxynucleoside triphosphates11. On digestion with restriction endonuclease BamHI, preparative gel electrophoresis allowed isolation of the desired fragments. The appropriate pairs of DNA fragments thus obtained were ligated together with T4 polynucleotide ligase and competent Escherichia coli cells were transformed. The nucleotide sequences in the regions containing the inserts are given in Fig. 1. In several cases, at the junctions between the plasmid DNA and the homopolymer inserts, a few unexpected base changes occurred. These changes were probably due to a low level of $3' \rightarrow 5'$ exonuclease activity in the calf thymus terminal transferase used in the construction of these plasmids.

An example of the gel electrophoretic patterns of several DNA samples relaxed in identical conditions is shown in Fig. 2a; lane 9 illustrates the band pattern observed when a single DNA, that of plasmid pLP222, is present. In lene 8, a second DNA (pLP219) shorter than pLP222 by three GC base pairs (bp) is mixed in. It can be readily seen that the band pattern of the longer plasmids shows a relative upward shift of ~ 0.3 times the interband spacing between topoisomers.

The set of covalently closed DNA samples prepared are all positively supercoiled in electrophoresis conditions¹², thus the faster migrating topoisomers have higher linking numbers than the slower migrating ones. Therefore an upward shift (that is, a reduction in the distance migrated) by 0.3 times the interband

Table 1 Helical repeats of $(dA)_n \cdot (dT)_n$ and $(dG)_n \cdot (dC)_n$

	DNA pair	Length difference (bp)	Shift observed	Corrected shift	Linking difference deduced	Calculated h ⁰ (bp per turn)
$(dA)_n \cdot (dT)_n$ inserts	pLP140/pLP144	4	0.44	0.42	0.42	10
(a)	pBR322/pLP119	19	0.00	0.91	1.91	9.9
	pLP119/pLP140	21	0.15	0.05	2.05	10.2
	pLP119/pLP144	25	0.59	0.47	2.47	10.1
	pBR322/pLP140	40	0.15	0.95	3.95	10.1

$(dG)_n \cdot (dC)_n$ inserts	pLP219/pLP222	. 3	0.28	0.27	0.27	11
	pLP219/pLP225	6	0.59	0.56	0.56	11
	pLP225/pLP234	9	0.88	0.84	0.84	11
	pLP222/pLP234	12	0.18	0.12	1.12	10.7
	pLP219/pLP234	15	0.47	0.40	1.40	10.7
	pBR322/pLP219	19	0.88	0.79	1.79	10.6
	pBR322/pLP222	22	0.17	0.06	2.06	10.7
	pBR322/pLP225	25	0.47	0.35	2.35	10.6
	pBR322/pLP234	34	0.35	0.18	3.18	10.7

Because of the particular construction of the homopolymer inserts and the base changes at some of the junctions, the homopolymer tracts do not make up the total length differences (second column) except for the pairs pLP119/pLP144, pLP219/pLP222 and pLP225/pLP234. For most of the other pairs sequences other than the homopolymers make up 5-10% of the total differences. Values of h^0 calculated are those of the total inserts. When the shift (third column) was < 0.2 or > 0.8 of the interband spacing, accurate measurements were obtained by the use of a common internal standard. For the pair pBR322/pLP119, for example, each member of the pair was measured against pLP144, and the same upward shift of 0.59 was observed. This shows that there is no shift between pBR322 and pLP119. For corrected shift an alternative way of making the length correction is to assume that the intrinsic length dependence of the electrophoretic mobility of a covalently closed topoisomer is the same as that for a nicked circular DNA. For DNAs of sizes similar to pBR322, the reduction in the distance migrated by a nicked circular DNA per bp increment in length was measured as 3.7×10^{-3} times the average spacing between two covalently closed topoisomers that differ by 1 in their linking numbers; this value was used to make the corrections in previous experiments. However, this procedure underestimated the correction, mainly because the topoisomers have migrated further than the nicked DNA, by a factor of ~ 1.2 on average. This results in a 20% underestimation. When this factor is taken into consideration, the two correction procedures give data which agree well. Note that although the absolute magnitudes of the helical repeats measured by the band-shift method are a function of the length correction factor, any differences between the helical repeats of particular sequences are not affected.

spacing agrees with a structure in which the 3-GC pair insert is in a right-handed helical form with a helical repeat of 3/0.3 or 10 base pairs per turn. The band-shift method cannot distinguish an upward fractional shift of 0.3 from a downward fractional shift of 0.7. Thus this single result by itself is equally consistent with the three GC pairs being in a left-handed helical form with a helical repeat of 3/0.7 or 4.3 base pairs per turn. Examination of several pairs of DNAs shows that consistent h^0 values are obtained only if the sense of the helical inserts is taken to be right handed. The same conclusion is arrived at with all other sequences examined.

Quantification of measurements for all pairs of DNAs were made on microdensitometer tracings of the negatives of gel photographs. A typical trace is shown in Fig. 2b to illustrate the resolution of the method. The observed shifts are given in column 3 of Table 1.

As described previously⁹, the band-shift method measures the displacement of one family of topisomers of a DNA with an x-bp insert relative to another family of topoisomers of the same DNA without the insert. Although for small inserts the electrophoretic mobilities of the topoisomers are affected by the inserts mainly by their effects on the deviations of the linking numbers of the topoisomers from the average linking number of the DNA in its relaxed state, the lengthening of a DNA per se does have a small but significant effect on its mobility. Correction for this intrinsic length effect is necessary to obtain data of high accuracy. Methods for making the length corrections have been discussed previously9. In one, the shift for each pair of DNAs is calculated from the average of the upward shift of the longer plasmid seen with both DNAs in the positively supercoiled form and the downward shift seen with both DNAs in the negatively supercoiled form. The intrinsic length effect enhances the upward shift but reduces the downward shift, thus the averaging cancels out this effect. An example is shown in Fig. 3

Using this method we have examined five pairs of DNAs with inserts 34-55 bp long and with sequences varying from

 $(dA)_n \cdot (dT)_n$ to $(dG)_n \cdot (dC)_n$. The average length correction factor calculated for these five pairs was 4.9×10^{-3} turns per bp with a s.d. of the mean of $\pm 0.2 \times 10^{-3}$. Deviation of the correction factor calculated for any one of the five pairs from that of the mean was found to be statistically insignificant, and the average was used for all the corrections.

The values for the calculated helical repeats after corrections for the length effect are given in the last column of Table 1. Clearly, when the lengths of the inserts are progressively increased the values for the helical repeat of GC inserts rapidly approach 10.7 ± 0.1 bp per turn. This is not significantly different from the helical repeat of 10.6 ± 0.1 bp per turn found for a 58-bp segment in the cro gene region of phage λ when the refined length correction reported here is applied to the published results. In contrast, the homopolymer $(dA)_n \cdot (dT)_n$ shows a helical repeat that is significantly different from those of the other sequences examined. The value 10.1 ± 0.1 bp per turn obtained for this sequence is the only one measured so far that agrees, within experimental error, with the classical 10-fold B-type helix of DNA.

The values measured are for the DNAs in electrophoresis buffer at room temperature. Effects of counterions and temperature on h^0 are well known but are <1% within the ranges generally considered to be physiological^{13,14}. The handedness of the helices is identical for all the sequences examined, and is presumably dexiotropic.

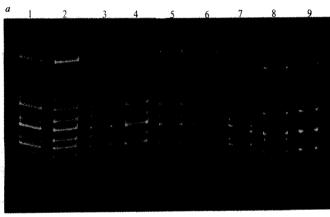

For sequences that are more or less random, the average helical repeat measured by the band-shift method for DNA in solution agrees remarkably well with that measured from the nuclease digestion pattern of DNA adsorbed on solid surfaces 15. The two very different methods give the same value of 10.6 ± 0.1 bp per turn. The theoretical calculation of Levitt 16 also gives a similar value for the helical repeat of DNA in solution.

There is a significant discrepancy between the solution measurements and X-ray diffraction studies of DNA fibres. Although DNA fibres show polymorphism when the counter-

ions and humidities are varied, the high-humidity form for DNAs of typical sequences is the B-type structure with 10 bp per turn. Recent measurements with highly solvated fibres gave the same results¹⁷.

There are various possible reasons why the fibre results do not agree with solution measurements. One potential complication brought into focus by a crystal structure of a dodecamer is the spatial writhe of DNA^{7,8}, and the plausible effect of lateral association of DNA molecules in a fibre on this writhe. Another explanation (suggested by D. M. Crothers) is that electric dichroism measurements of DNA in solution indicate that the structure is sensitive to aggregation induced by heavy metal ions. The magnitude of the dichroism in the absence of heavy metal ions can be interpreted by the structure calculated by Levitt¹⁶ with the base pairs assuming propeller twists and a 10.6-bp periodicity. In the aggregated state, the magnitude of the transient dichroism changes to that of a B-type structure with the base pairs almost perpendicular to the helical axis. A third possibility is that packing forces in fibres or crystals tend to favour structures with integral helical repeats¹⁸. Even in highly wetted fibres, the packing forces might be significant relative to the free energy differences among different polymorphic forms.

In the case of the homopolymer sequence $(dA)_n \cdot (dT)_n$, the solution measurements agree with fibre diffraction studies. The agreement between the helical repeat of poly(dA) · poly(dT) from fibre diffraction measurements and our solution measurements provides a clue to the reason for the disagreements between other sequences. The sequence $(dA)_n \cdot (dT)_n$ seems to be unique in its inertness to environmental effects ¹⁹⁻²². Both IR and fibre diffraction studies indicate that the B-type to A-type transition which can be induced for the

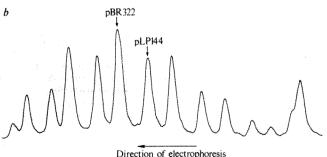

Fig. 2 a, Electrophoretic patterns of DNAs. DNA samples were relaxed overnight at 0 °C with calf thymus topoisomerase I in 10 mM Tris-HCl pH 8, 0.2M NaCl, 0.1 mM EDTA. The reaction was stopped and the enzyme removed by extraction with neutralized phenol. Electrophoresis in 0.7% agarose was carried out at room temperature after dialysis of the DNA samples against the electrophoresis buffer (90 mM Tris-borate pH 8.3, 2.5 mM EDTA). Plasmids present in the gel lanes are: 1, pLP225/pLP140; 2, pLP140/pLP144; 3, pBR322/pLP144; 4, pBR322/pLP225; 5, pLP219/pLP234; 6, pLP219/pLP225; 7, pLP222/pLP225; 8, pLP219/pLP222; 9, pLP222. b, Microdensitometer tracing of the negative for the electrophoretic pattern of the pair of DNAs pBR322/pLP144 (lane 3 of a).

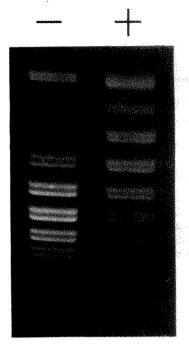

Fig. 3 Electrophorectic gel pattern of a mixture of pTR161 and pTR182, two DNAs that differ by an insert of 53 base pairs of a sequence in the cro gene region of phage λ^9 . Relaxation of the DNAs was the same as described in Fig. 2 legend except that during the topoisomerase I reaction the sample on the left contained ethidium. The covalently closed DNAs in the left lane are negatively supercoiled whereas those in the right lane are positively supercoiled. The DNAs were identified by comparing the gel patterns with those of positively and negatively supercoiled marker

other sequences does not occur for poly(dA) · poly(dT). The sensitivity of other sequences to environmental effects and packing forces may underlie their polymorphism in fibres and crystals, and cause structural differences between the condensed and soluble states.

The possible biological significance of different helical geometries associated with DNAs of different sequences has been widely discussed. The solution measurements have the advantage that the DNA is in a more physiological state and is free from packing forces. Our results clearly demonstrate that the sequence (dA), (dT), has a distinct helical geometry in solution. We hope that the method described here will find increasing application in cases where the molecular geometries of particular sequences are thought to have significant biological

We thank Professors D. M. Crothers and R. E. Dickerson for communicating their results before publication, and those of our colleagues who provided us with various enzymes. This work was supported by NSF grant PCM 78-05892.

Sequence-dependent helical periodicity of DNA

D. Rhodes & A. Klug

MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK

We have recently described a new approach to measuring the helical periodicity of random sequence DNA in solution1. It consists of binding short, stiff pieces of DNA to various flat surfaces and using DNase I to probe the most accessible phosphodiester bonds. The differences in length of the fragments produced are measured with high precision to give the helical repeat directly. This approach has now been extended to study the periodicity of defined-sequence DNAs using another enzyme, micrococcal nuclease, as well as DNase I. We find the helical repeat of poly(dA-dT) to be $10.5 \pm < 0.1$ base pairs (bp), a value very close to that found earlier by us for randomsequence DNA, 10.6±0.1 bp, and confirmed here. Poly(dA).poly(dT) exhibits a distinctly different helical repeat, 10.0 ± 0.1 bp.

In our earlier work we used two different experimental approaches. The first used short DNA fragments of defined length, nominally 140 bp extracted from nucleosome cores, and the ³²P label incorporated beforehand at the 5' termini. This method, besides giving accurate distances between DNase I cutting sites, also enables the probability of cutting at each site along the length of the DNA fragment to be determined. The second used DNA fragments with a wide distribution of lengths, an average of ~200 bp, and the ³²P label was introduced after DNase I digestion. As a less laborious alternative, the 32P label has now been incorporated by nick translating each DNA sample. As fragments of poly(dA-dT) and poly(dA) poly(dT) of defined length are not readily available, double-stranded fragments a few hundred base pairs long were produced by shearing samples of calf thymus DNA (Sigma, 'highly polymerized'), long poly(dA-dT) and poly(dA).poly(dT) (both BCL Boehringer) in a sonicator2, which gives a broad fragment-length distribution of

Figure 1a, b and c show the results from experiments where DNA. poly(dA-dT) and poly(dA).poly(dT) were immobilized on calcium phosphate microcrystals and mica powder, then lightly digested with micrococcal nuclease or DNase I and the products fractionated by polyacrylamide gel electrophoresis3,4 The autoradiographs show patterns of fine bands, each band representing single-stranded fragments differing in size by one nucleotide. The intensities of the fine bands vary, showing band maxima at regular intervals ~10 bases apart. A set of intense fine bands represents a set of fragments produced by cutting with the nuclease at two different groups of accessible phosphodiester bonds ('sites') in the same DNA molecule. The 'ladder' formed by successive groups of fine intense bands is a direct visualization by the nuclease of the helical repeat.

The average distance between nuclease cutting sites can be obtained by counting the number of fine bands between maxima and then dividing by the number of maxima traversed. The calculation can easily be carried out from the densitometer tracings of the autoradiographs shown in Figs 2 and 3. For example in Fig. 3, in the densitometer tracing of poly(dA).poly(dT) digested with DNase I, the number of fine peaks between F3 and F10 is 70, giving a value of 70/7 = 10.0bases

For random-sequence DNA (Fig. 1a) the distance between DNase I cutting sites is 10.5-10.6 bases as found previously¹. The same value was obtained using micrococcal nuclease (not shown), but here the lengths of a proportion of the fragments produced is gradually reduced as the digestion proceeds. This is in contrast to the case of the two synthetic (A, T) polymers, where all fragments are progressively reduced in length (see below). We interpret the difference as due to the relative resistance to micrococcal nuclease⁵ of (G,C) stretches, compared with (A.T) stretches, present in random sequence DNA. The mechanism of trimming of DNA fragments has consequences for the production of nucleosome cores from

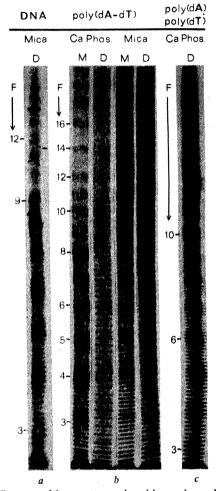

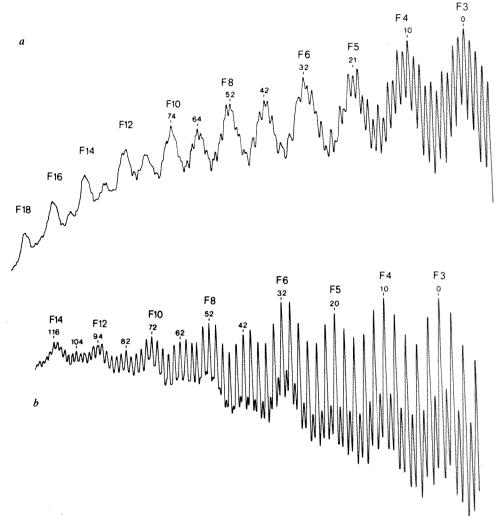

Fig. 1 Patterns of fragments produced by nuclease digestion of three DNAs immobilized on flat surfaces. After nick translation in the presence of $[\alpha^{-32}P]$ dATP (ref. 23), each DNA sample was extracted, precipitated and the DNA and poly(dA-dT) precipitates 20 mM Tris pH 8.0 and 60 mM Poly(dA),poly(dT) was dissolved in 20 mM Tris pH 8.0 only, because even low concentrations of salt tend to favour the formation of triple strand helices²⁴. Finally, the two synthetic polymers were annealed at 40 °C for 10 min and then stored at 5 °C. The purity of the synthetic DNAs was checked by nearest neighbour analysis. The calcium phosphate surface and the mica powder were prepared as described earlier1, except that the concentration of the buffer in which the mica is resuspended has been halved, to reduce the destabilizing effect that Mg²⁺ ions have on the double helices of (A. T) polymers²⁵ a Autoradiography of readon services. a, Autoradiographs of random sequence DNA fragments from electrophoresis in a high-resolution denaturing gel made with 8% acrylamide and 1.35% methylenebisacrylamide. This system can resolve random sequence fragments differing in size by one nucleotide3. b, Poly(dA-dT); c, poly(dA).poly(dT) fragments from electrophoresis in denaturing gels made with 6% acrylamide and 0.3% methylenebisacrylamide, as used in DNA sequencing⁴. All nuclease digestions were carried out at 20 °C. D signifies DNase I and M signifies micrococcal nuclease. F stands for a set, or group, of fragments and the number indicates the size class, for example, F3 represents fragments of ~ 30 bases in length. The gel tracks shown in b have been assembled from the same gel, containing additional experiments not shown here.

Fig. 2 Densitometer tracings of the autoradiograph shown in Fig. 1b, (first two lanes); poly(dA-dT) digested with a, micrococcal nuclease; and b, DNase I. The fine peaks which represent poly(dA-dT) fragments differing in size by one nucleotide are numbered from the centre of band F3. In a, because of the base specificity of micrococcal nuclease, there is an alternation of intensity in the fine peaks and in b, because of the base specificity of DNase I (see text), fine peaks every two nucleotides dominate the pattern.

chromatin and will be discussed elsewhere (M. Cockell, D.R. and A.K., in preparation).

The results from a typical experiment on poly(dA-dT) immobilized on two different surfaces and digested with micrococcal nuclease or DNase I are shown in Fig. 1b. The intensity variations between successive fine bands is caused by the particular base specificities of the two nucleases used. Micrococcal nuclease cleaves poly(dA-dT) in solution at Ts with only a slight preference over As⁶ whereas DNase I cleaves almost exclusively at Ts, producing a large proportion of fragments differing in size by two nucleotides⁷ (Fig. 2a,b). The sets of fragments produced by micrococcal nuclease (lanes M) lie one or two nucleotides below the sets of fragments produced by DNase I (lanes D). This reduction in length depends on the extent of digestion, but all fragments seem to be reduced in length to an equal extent. Consequently, the distance between micrococcal nuclease cutting sites remains essentially constant.

The helical repeat of poly(dA-dT) bound to calcium phosphate, obtained directly from the densitometer tracings (Fig. 2a,b), is 10.5 bp with both nucleases. The intensity distribution in Fig. 1b (first two lanes) and Fig. 2a,b indicates that the helical periodicity is very close to 10.5 bp. There is an alternation in intensity between successive sets of intense fine bands, especially visible in the longer fragments, for example, F10 and F18. This shows that the repeat length seen by the enzyme is two helical turns corresponding to an exact integral number of base pairs $(10.5 \times 2 = 21)$. Poly(dA-dT) bound to mica showed a slightly lower helical periodicity (Fig. 1b, last two lanes). The alternation of the intensities of the longer fragments is not so evident and the densitometer tracings (not shown) give a helical repeat of 10.4 bases.

Figure 1c shows the result of an experiment with the third polynucleotide, poly(dA), poly(dT), bound to calcium phosphate

and digested with DNase I. The densitometer tracing in Fig. 3 shows that the helical periodicity of poly(dA).poly(dT) is distinctly different from that of DNA or poly(dA-dT). The repeat length of the fragments produced is 10.0 bases. The periodicity observed using micrococcal nuclease is the same as that found with DNase I, but because the fragments are reduced in size very rapidly the measurements vary from site to site and are therefore less accurate (not shown). We were unable to obtain a ladder reflecting the double-helical screw from poly(dA).poly(dT) immobilized on mica. Presumably, when the polymer comes into contact with Mg²⁺ present in the mica suspension buffer, its double-helical nature is lost because of the propensity of poly(dA).poly(dT) to form triple-stranded helical structures?

The enzyme digestion method for determining the helical periodicity of DNA is simple, direct and requires no corrections. The accuracy of the measurements of the distance between

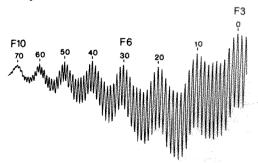

Fig. 3 Densitometer tracing of the autoradiograph shown in Fig. 1c. The fine peaks which represent poly(dA) poly(dT) fragments differing in size by one nucleotide are numbered from the centre of F3 to F10.

nuclease cutting sites depends mainly on the length of the largest DNA fragments that can be resolved to a resolution of a single nucleotide in the gel electrophoresis system, that is, on the number of helical repeats counted. The resolution of the homopolymer fragments is very good because the gel electrophoresis system used for sequencing DNA can be used⁴, but the random-sequence DNA fragments cannot be fractionated to the same resolution³. In our earlier paper on random-sequence DNA we mentioned that the changes caused by cation type and concentration and temperature on the screw of DNA^{10,11} would not be >0.1 bp per turn. In the present study with poly(dA-dT), where the precision of the results is higher, we find just such a change. The decrease in screw in the presence of millimolar Mg^{2+} is about 1% = 0.1 bp and is consistent both in sign and magnitude with previous work by others¹¹

The results we have obtained demonstrate that the helical periodicity of DNA depends on the nucleotide sequence. Thus, the number of 10.0 bp per turn of the poly(dA).poly(dT) double helix in solution is distinctly different from the value of 10.4-10.6 we found for poly(dA-dT) and random-sequence DNA. These values are in good agreement with measurements by Wang who, using a completely different experimental approach from ours, has reported a value of 10.5 bp for DNA and 9.9 for poly(dA).poly(dT)^{12,13}.

It is not surprising that the same helical screw is found for random-sequence DNA and poly(dA-dT) because the former must contain, on average, equal numbers of purine and pyrimidines on each strand. The different helical periodicity observed for poly(dA).poly(dT) can perhaps be correlated with physicochemical studies which suggest that this polymer is different in some way from all other DNAs studied14. Poly(dA).poly(dT) fibres give essentially the same B-form X-ray diffraction pattern as other DNAs, but, unlike all other DNAs studied, no conditions have been found for its transition to a different form¹⁵. Furthermore, poly(dA).poly(dT) is the only DNA with a UV circular dichroism spectrum which does not fit a simple additivity rule accommodating many different DNA duplexes16

The distinctly different helical screw we have found for poly(dA).poly(dT) could be of some biological significance. The previous finding that nucleosomes cannot be reconstituted from poly(dA).poly(dT), but are easily obtained from reconstitution with poly(dA-dT) or DNA^{17-19} , was previously explained by the high salt in the reconstitution system used, disproportionating poly(dA).poly(dT) into triple helical structures. However, the present results suggest an alternative explanation. There are also examples where the A+T-rich spacer regions between genes, such as the 5S genes of yeast^{20,21} and the histone genes of sea urchin²², contain long runs of As. Although these findings might not be coincidental, it is premature to conclude that such stretches of poly(dA).poly(dT) would exclude nucleosomes directly.

In vivo consequences of plasmid topology

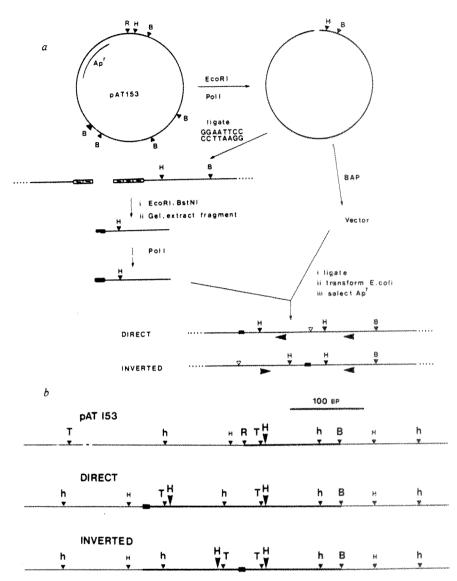

David M. J. Lilley

Molecular Genetics Department, Searle Research Laboratories, Lane End Road, High Wycombe HP12 4HL, UK

The topology and physical chemistry of closed circular DNA molecules are well understood, but the significance for events within living cells is less well appreciated. It has been demonstrated recently 1-3 that the torsional constraint which arises from negative supercoiling (that is, reduction of linkage) can induce localized novel secondary structure in isolated plasmid and phage DNA. Inverted repeats adopt hairpin-loop structures not found in relaxed DNA. This structural perturbation might be expected to have functional significance within the living cell. but clearly this requires that the torsional free energy be available for unhindered partition between alterations of twist and writhe. Microheterogeneity in DNA structure has recently attracted considerable interest, especially with regard to left-handed sections of duplex⁴⁻⁶. The inverted repeats identified as sites of hairpin formation are relatively small, with stems of 13 base pairs (bp) or less. Whilst these hairpins could result in a relaxation of $\sim 10\%$ of the plasmid supercoiling energy, it was of considerable interest to try to construct stem-loop features about 10 times larger so as to study the topological consequences. In the cloning experiment described here, designed to produce direct or inverted 130-bp repeats depending on insertional orientation, no inverse species could be discovered, and deletion events were frequent. It is concluded that the inverted repeat deprives Escherichia coli of its antibiotic resistance. Cruciform adoption by the inverted species can totally relax the torsional constraint in the plasmid. These experiments highlight the importance of topological considerations in the genetics of closed circular DNA, and confirm the availability of torsional constraint in vivo.

Figure 1a shows the experimental basis of the investigation. A 130-bp EcoRI, BstNI fragment of pAT153 (ref. 7) was inserted back into the parent plasmid to generate either a direct repeat, or an inverted repeat with a 6-bp central loop, depending on orientation. Resulting colonies were screened by restriction enzyme analysis of plasmid DNA, using the predicted restriction maps shown in Fig. 1b. The most straightforward screening procedure involved HindIII digests of plasmid mini-preparations⁸ from each colony. As pAT153 has a single HindIII site at 29 bp (relative to EcoRI at 0 bp), the direct repeat recombinant should give a 130-bp fragment, and the corresponding fragment size from the indirect repeat molecule should be 70 bp. Figure 2a shows a typical restriction cleavage analysis of some recombinant plasmids. Analysis of 67 ampicillin-resistant colonies revealed that these comprised 21 recyclized parent plasmids, 25 direct repeat species, no inverted repeat species and 21 deletants. The most important comparison is that between direct and inverted repeats of 25/0. As the probability of insertion in either orientation is 50%, it is quite clear that selection at another level is operating in this experiment. A rather high level of deletants was observed (31%), several of which seem to be mutations which disrupt the symmetry of what would otherwise be inverted repeats. This again implies that it is the symmetry of the inverted repeat which is responsible for its non-viability. The high level of recyclized vector (31%) arises from the inherent low efficiency of blunt-end ligation reactions, coupled with the removal of inverse orientation events from the statistics. The statistics show clearly that an inverted repeat of unit length 136 bp confers lethal properties on pAT153. This could arise by interference with the mechanism of plasmid replication or the expression of the ampicillin-resistance gene, such that resistance is no longer conferred on the host bacterium. The act of insertion per se is clearly not responsible for the effect, because the direct

a, Schematic outline of the construction of recombinant molecules derived by reinsertion of the 130-bp EcoRI, BsfNI fragment of pAT153 (ref 7) into the flush-filled EcoRI site of pAT153, with hexanucleotide asymmetric joining section. pAT153 was cleaved by EcoRI and the resulting 5' extensions 'filled in' using 2 units of the Klenow fragment of E. coli DNA polymerase I (Boehringer) in 50 mM Tris pH 7.5, 10 mM MgCl₂, 1 mM β -mercaptoethanol with 0.25 mM of each of the four deoxynucleotides for 30 min at 15 °C. One-quarter of this was dephosphorylated using 20 µg bacterial alkaline phosphatase (F grade, Worthington) in 20 mM Tris pH 7.5, 0.1% SDS for 30 min at 37 °C, for subsequent use as cloning vector. EcoRI linker (Collaborative Research) was 5 phosphorylated in two stages. 2.5 µg of the doublestranded octanucleotide were incubated in 50 mM Tris pH 7.5, 10mM MgCl₂, 5 mM dithiothreitol, 0.1 mM spermidine using 100 μCi of 5,000 Ci mmol⁻¹[γ-³²P]ATP (Amersham) and 3 units of T4 kinase (New England Biolabs) at 37 °C for 60 min, followed by addition of unlabelled ATP to 1 mM and further kinase and incubation for an additional 60 min. The phosphorylated octanucleotide was ligated to the remainder of the flush-ended EcoRIcleaved pAT153 by the blunt-end ligation procedure19, using 0.2 units of T4 DNA ligase (Bethesda Research) in 50 mM Tris pH 7.5, 10 mM MgCl₂, 20 mM dithiothreitol, 1 mM ATP for 2 h at 15 °C. After EcoRI, BstNI cleavage, the fragments were resolved on 5% polyacrylamide gel electrophoresis²⁰ and the 136-bp fragment removed by homogenization and extraction in 0.5 M NH₄-acetate, 10 mM Mg-acetate, 0.1% SDS, 0.1 mM EDTA²¹ at 37 °C, followed by binding to DEAE cellulose (Whatman), washing, elution and ethanol precipitation. After polymerase filling to give flush ends, this fragment was blunt-end ligated into the flush-ended EcoRI -cleaved and dephosphorylated pAT153. After ligation, DNA samples were diluted to 100 µl in 10 mM Tris pH 7.5, 10 mM CaCl₂ and 10 mM MgCl₂ and used to transform 200-µl aliquots of CaCl₂-shocked *E. coli* K12 HB101 (ref. 22) as described previously²³. After 20 min at 37 °C in L broth containing 100 µg mlcarbenicillin (Pyopen), 200-µl aliquots were plated on to agar containing 100 µg ml⁻¹ carbenicillin and carbenicillin and incubated at 37 °C for 16 h. (All restriction enzymes used in this study were from New England Biolabs or Bethesda Research Laboratories, and used as directed.) Key: R. EcoRI site; H. HindIII sites; B. BsfNI sites; BAP, dephosphorylation using bacterial alkaline phosphatase; PolI, flush-filling using DNA polymerase I (Klenow fragment); Apr, resistance to ampicillin. The rectangular boxes represent the repeats do not possess these properties, and thus we are left with the symmetry created by inverse insertion. However, the symmetry cannot be solely responsible for the lethal properties because smaller inverted repeats occur in ColE1 and pBR322^{1,2} and in recombinants derived from these plasmids³. The major

synthetic EcoRI linker fragment, and the filled box represents the double-stranded AATTCC unit. Filled triangles denote restriction enzyme sites, and open triangles denote restriction sites deleted during construction. b, Restriction maps of the EcoRI region of pAT153, and calculated maps for the direct and inverse recombinants, all derived from the sequence of pBR322 (ref. 24). Key: R, EcoRI; H, HindIII; B, BstNI; T, TaqI; H (smaller), HaeIII; h, HhaI. The thicker line denotes sequences between the EcoRI and BstNI sites of pAT153 which become duplicated in the recombinants. The filled boxes represent the hexanucleotide joining section.

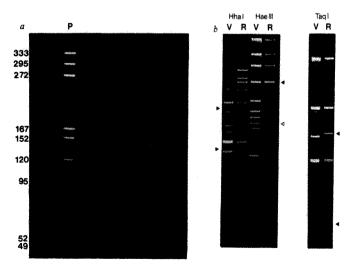

Fig. 2 Analysis of recombinants by restriction enzyme cleavage. a, HindllI cleavage of plasmid mini-preparations grown from individual colonies. The marker fragments (P) are HaeIII-digested phage PM2 DNA. Colonies were picked into 1 ml L broth solutions containing 100 µg/ml⁻¹ carbenicillin and grown at 37 °C for 16 h in the absence of chloramphenicol. DNA was prepared using a modification of the alkaline preparation method^a where all standing times were reduced to 5 min. After two ethanol precipitations and an optional phenol extraction, the DNA was sufficiently pure to be digested by restriction enzymes. This method gives a low chromosomal DNA background but to visualize small DNA fragments it was necessary to remove contaminating RNA by inclusion of 50 µg ml⁻¹ RNase A (Sigma, preincubated at 95 °C for 10 min to remove potential DNase activity) in the restriction enzyme digestion. b, Detailed analysis of one clone containing a full-length 136-bp insertion. A 100-ml culture was grown from a 1-ml overnight incubation of one full-length recombinant, for 16 h at 37 $^{\circ}$ C in L broth containing 100 μg ml $^{-1}$ carbenicillin but in the absence of chloramphenicol amplification. Plasmid DNA was purified from cell lysates by banding in caesium chloride²⁵. Key: V, pAT153 digests; R, recombinant digests. Solid triangles denote new (or double intensity) fragment bands; open triangles denote bands missing from the recombinant digests. Note that these digests unambiguously confirm the orientation of the inserted DNA, and the increase in length of the 206-bp Hhal and 368-bp Tagl fragments confirms the presence of the joining hexanucleotide

difference between the inverted repeat created in this experiment, and those found in ColE1 and pBR322, is one of size. The ColE1 repeat has a unit size of 13 bp, whereas that in the potential pAT153 recombinant is 10-fold larger-130 bp.

I have observed previously that small inverted repeats present in supercoiled circular DNA are centrally hypersensitive to S₁ nuclease, implying the adoption of hairpin-loop structure. On forming a cruciform type of structure an alteration of twist occurs for the molecule, given by

$$\Delta T w = n/10.4 \tag{1}$$

where n is the total number of base pairs involved in the formation of the hairpin. (The number of 10.4 is derived from an estimate of the twist of solution DNA being 10.4 bp per helical turn⁹.) The parameters which describe the topological properties of supercoiled DNA are related by the expression

$$\Delta Lk = \Delta Tw + Wr \tag{2}$$

where ΔLk is the alteration in linkage from the most relaxed topoisomeric conformation, and Wr is the writhing number. The linking number for pAT153 has been measured as 18±1 (Fig. 3), which equation (2) shows must be partitioned between alteration of twist or writhe, either of which is energetically unfavourable. However, the twist alteration produced by cruciform formation allows the rest of the molecule to 'relax' by the extent

$$R = \frac{-n}{10.4 \ \Delta Lk} \times 100\% \tag{3}$$

thus, for ColE1 $(n = 30 \text{ and } \Delta Lk \simeq -27)^{12}$ a relaxation of twist and writhe of 11% should occur. For the inverse recombinant pAT153 species relaxation becomes 142% (n = 266), that is, the molecule can be totally relaxed. This, then, is the likely basis of the lethal properties of these large inverted repeats.

Further examples of selection against inverted symmetric units can be found in the literature 13.14, and another example has recently been noted in this laboratory (W. Tacon, unpublished results), when it was found that only tandem repeats of a 111-bp fragment could be obtained in a multiple-copy cloning experiment. One explanation previously proposed¹⁴ was that the symmetry might facilitate strand switching during replication. However, there is no a priori reason that such a process should occur only in longer inverted repeats. It seems more likely,

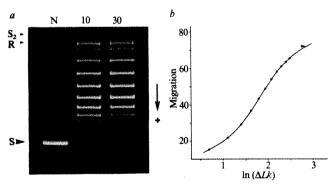

Fig. 3 Measurement of the relative linking number (ΔLk) of pAT153 by gel electrophoretic resolution of partial topoisomerizations^{26,27}. a, 1.2% agarose gel electrophoresis (room temperature) of native supercoiled and partially relaxed pAT153. 0.8 µg of pAT153 was incubated with 2 units of Agrobacterium tumefaciens topoisomerase (Bethesda Research) at 37 °C in 20 mM Tris pH 7.8, 2 mM MgCl₂, 7 mM β-mercaptoethanol for the times indicated (min), followed by electrophoresis at 50 V for 16 h in 40 mM Tris pH 8.0, 5 mM Na-acetate, 1 mM EDTA²⁸. Key: N, fully supercoiled pAT153; S, R and S₂, positions of migration of fully supercoiled monomer, nicked monomer and supercoiled dimer species. b, Extrapolation of migration of topoisomers to that of the native supercoiled pAT153 (shown by the arrow) indicates that $\Delta Lk = -18$. Migration of individual topoisomers measured by microdensitometer scanning of photographic negatives. The were assigned by comparison of identical topoisomerizations on agarose gels run at room temperature and 5 °C (ref. 16). Thus, the most slowly resolved topoisomer in a was assigned to $\Delta Lk = -2$. A small error (estimated to be ± 1) may result from the extrapolation procedure.

therefore, that the topological effects are the basis of these observations. Another instance of such properties was noted by Gellert et al. 15, who were unable to propagate a circular dimer of the longer EcoRI, BamHI fragment of pBR322. Another example may be found in a study of post-transformational rearrangement in modified pSM19035 (ref. 16), where manipulations designed to generate a large perfect inverted repeat resulted in spontaneous deletion events which removed the centre of symmetry.

Several consequences follow from these observations. First, the strong selection against inverted repeats demonstrates that topological effects are operative on DNA within the living bacterium, that is, that the torsional constraint arising from linkage reduction by gyrase is 'available', rather than being locked up in writhing around histone-like proteins. This energy is available to drive processes requiring strand separation, such as transcription^{17,18}, and possibly the alteration of DNA secondary structure 1-3. It is therefore perhaps not surprising that the (possibly transient) release of this free energy into cruciform structures has deleterious consequences. Second, the present study demonstrates that inverted repeats can strongly influence the functional properties of supercoiled molecules. The difference between the stable direct species and the unstable inverted species constructed in these experiments is quite subtle—the reversal of polarity of 130 bp in a 3.7-kbp molecule at a region distinct from both ampicillin-resistance and replication functions. Yet this modification in some way deprives the cell of its resistance to the antibiotic. Finally, these studies have practical significance, for they imply that the topological consequences of certain cloning operations should be considered. Thus, 'head to head' dimers of fragments above a limiting size are likely to be impossible to clone. Furthermore, plasmid 'libraries' may be incomplete if inverted repeats are present in the original nucleic acid cloned.

The size limitations on cloning ability are imprecise at present, but some limits may be set. The stability of cruciform structures will be proportional to stem length, but inversely proportional to loop size^{1,3}, whereas the topological consequences depend on the size of the whole feature. Stem sizes of 9-13 bp do not result in plasmid instability¹, whilst we have noted in this laboratory that 30-bp duplications (R = 32%) cannot be cloned inverted in pAT153. However, longer inverted repeats have been propagated where the loop size is 12 nucleotides. As I have noted previously³, the symmetry requirements for cruciform structure formation are stringent.

I thank many of my colleagues at Searle, especially Drs W. Tacon and M. Houghton, and also Professor D. Sherratt for useful discussion.

Sequence homologies between tonin, nerve growth factor γ -subunit, epidermal growth factorbinding protein and serine proteases

Claude Lazure, Nabil G. Seidah, Gaétan Thibault, Roger Boucher*, Jacques Genest & Michel Chrétien

Clinical Research Institute of Montreal, 110 Pine Avenue West, Montreal, Quebec, Canada H2W 1R7

Tonin¹, a protein isolated from rat submaxillary gland, has interesting proteolytic activities. It is able to liberate angiotensin II from angiotensinogen (or a shorter synthetic tetradecapeptide corresponding to the first 14 residues) and from angiotensin I; it is also able to release peptides from β -lipotropin (β -LPH), corticotropin (ACTH) and their common precursor proopiomelanocortin (POMC) leaving intact the β -endorphin and the Met-enkephalin entities^{2,3}. Here, we describe the sequencing of 95 of the 272 amino acids of tonin. Our results reveal extensive sequence homology of tonin with the γ -subunit of nerve growth factor (NGF) and epidermal growth factor (EGF)-binding protein (both of which also have proteolytic activities), and also with serine proteases.

Tonin is a single polypeptide chain of 272 amino acids having a molecular weight of 28,700; sequence analysis has revealed isoleucine and proline at the NH₂ and COOH termini respectively⁴. We have now extended the NH₂-terminal sequence up to 65 cycles with excellent repetitive yield while identifying blanks and uncertain residues in the previously reported sequence, as shown in Fig. 1a. In addition, we identified 30 other residues in a cyanogen bromide fragment, giving the definitive sequence of 35% of the molecule (Fig. 1b). While this work was being carried out, the sequence of the γ -subunit of mouse NGF became available⁵, making it possible to compare the amino acid sequences.

As indicated in Fig. 2a, alignment of the first 65 residues of the γ -subunit and tonin reveals only 15 differences—77% homology. Furthermore, the sequence Val-Leu-Thr-Ala-Ala-His-Cys, which is found in all serine proteases except haptoglobin, a recently proposed serine protease homologue⁶, is present in rat tonin; it does contain a conservative substitution, namely the isoleucine at position 35 in place of the common leucine residue. This segment is very important because it contains the histidine residue typical of the active site of all serine proteases. The cysteine residue at position 24 is part of the disulphide loop maintaining the proper orientation of the histidine residue. The relationship between rat tonin and serine proteases can also be seen by comparison of the first 65 residues with known sequences: the homology with rat tonin is highest for pancreatic enzyme kallikrein⁷ (55%) and trypsin⁷ (48%), with other serine proteases slightly less homologous⁶⁻¹³.

Comparison of the NH₂-terminal sequence of a cyanogen bromide fragment of tonin with positions 95–124 of the γ -subunit (Figs 1b and 2b) also reveals 21 identical positions out of 30, thus showing a striking similarity (70%) between rat tonin, γ -subunit and serine proteases.

Although the present results reveal only a partial (35%), but definitive, sequence of rat tonin, it is nevertheless clear that tonin isolated from rat submaxillary gland is very closely related to the γ -subunit of mouse NGF and also probably to the EGF-binding protein. Our data do not show conclusively that tonin represents a variant of the γ -subunit of the rat NGF because NGF could not be detected in the submaxillary gland of the rat ^{14,15}; however, this possibility cannot be ruled out. Also interesting is the fact that the isolated tonin is a single poly-

Fig. 1 a, Automatic NH2-terminal degradation of reduced and alkylated rat tonin. Sequencing was carried out on 2.6 mg (87 nmol) of protein using 3 mg of polybrene precycled seven times and a 0.3M Quadrol programme on an updated Beckman 890B sequenator fitted with a cold trap. Phenylthiohydantoin (PTH) derivatives were obtained after conversion in methanol/HCl using in-line sequemat Po autoconverter. Separation and quantification were carried out by HPLC using an ultrasphere-ODS column and a tetrahydrofuran acetonitrile gradient. Quantitative yields of PTH-amino acids corrected for background and normalized to PTH-norleucine internal standard are illustrated as a function of residue number. The slope and intercept were obtained by a linear regression analysis on selected stable PTH-amino acids. Repetitive yield thus obtained was 95.2% while the carry-over never exceeded 1% except for Glu and Asp residues which are retained by the polybrene. b, Automatic NH2-terminal degradation of a reduced and alkylated (using ³H-iodoacetic acid) fragment of rat tonin obtained by cyanogen bromide cleavage. Sequencing was carried out on ~10-15 nmol using the conditions described above; the repetitive yield for that sequence was 89%.

No. cycles

peptide chain comprising 272 amino acids, whereas the γ -subunit, as reported, is composed of 233 amino acids distributed in what seems to be two or three chains linked by disulphide bridges. This observation supports Thomas et al.'s proposal's that a limited, perhaps autocatalytic, proteolysis of a single-chain form of γ -subunit generates a two- or three-chain form. Rat tonin is clearly related to the serine proteases family, especially to trypsinogen, kallikrein and plasminogen. On the other hand, the substrate specificity of this enzyme seems to be

^{*} Deceased

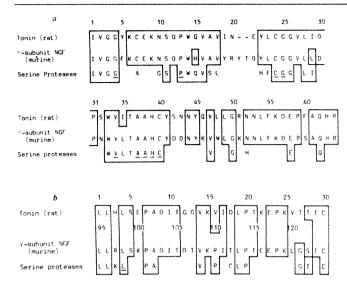

Fig. 2 a, Comparison of the amino acid sequence (in the singleletter code, ref. 16) of the NH₂-terminal portion of rat tonin with corresponding segment of y-subunit of mouse NGF as determined by Thomas et al.⁵ and with conserved segments of serine proteases according to Dayhoff⁷. The underlined residues correspond to invariant position in the known sequence of all serine proteases. b, Comparison of the amino acid sequence of a cyanogen bromide fragment of rat tonin with residues 95-124 of y-subunit of mouse NGF and conserved segments of serine proteases.

quite different from the arginine-specific activity of NGF γ subunit and EGF-binding protein because it is able to cleave after specific arginine residues and after suitably located lysine, phenylalanine, tyrosine and tryptophan residues depending on the pH used for the digest^{2,3}. For example, at pH 5.0 it can selectively cleave the pro-opiomelanocortin precursor to yield intact ACTH involving an arginine and phenylalanine cleavage at the NH₂ and COOH termini respectively. Thus, this enzyme expresses a selective chymotryptic-tryptic-type activity. The digestion studies clearly indicate the importance of the conformation of the substrate in directing the site of cleavage^{2,3}. Originally, it was proposed that tonin might be involved in the local generation of angiotensin II in tissue; its newly found similarity with NGF γ -subunit and EGF-binding protein suggests other possible roles for this enzyme and its substrate specificity.

This work was supported by the MRC of Canada (PG-2). We thank Dr Bradshaw for making available the preprint manuscript concerning the sequence of the NGF γ-subunit, Miss J. Hamelin and M. G. De Serres for technical assistance, and Mrs D. Marcil for typing the manuscript.

Methionyl-tRNA synthetase shows the nucleotide binding fold observed in dehydrogenases

J. L. Risler, C. Zelwer & S. Brunie

Centre de Génétique Moléculaire, 91190 Gif sur Yvette, France

A striking common structural feature has emerged from the comparison of the X-ray crystallographic studies of several dehydrogenases. In lactate dehydrogenase¹, soluble malate dehydrogenase², alcohol dehydrogenase³ and glyceraldehyde-3-phosphate dehydrogenase⁴ similar foldings have been described in the region which binds the coenzyme NAD, whereas no significant similarities were observed in the chemical sequences. The occurrence of a characteristic 'nucleotide binding fold' (the so-called Rossmann fold) has also been observed in horse muscle phosphoglycerate kinase⁵, in phosphorylase^{6,7} and, with some topological deviations, in other kinases 8-11 as well as in the flavin-binding domain of flavodoxin12. If one assumes that these structural homologies are the result of a divergent evolutionary process, it is then tempting to predict a similar pattern of structure-function relationship in other nucleotide-binding proteins, in particular in aminoacyl-tRNA synthetases. We show here that methionyl-tRNA synthetase does show the same nucleotide binding fold.

Native Escherichia coli methionyl-tRNA synthetase, a dimer of molecular weight (MW) 172,000, has never been obtained in a crystalline form. However, a fully active monomeric fragment which can be prepared by a controlled proteolysis¹³, crystallizes in space-group P2, with a = 78.1 Å, b = 46.2 Å, c = 87.9 Å, $\beta = 108.8^{\circ}$. The crystals contain one molecule of MW 64,000 per asymmetric unit14. The structure of this active fragment has been determined at 2.5 Å resolution by the multiple isomorphous replacement (MIR) method using five heavy-atom derivatives. The diffracted intensities were recorded photographically with an oscillation camera and measured using a rotating drum densitometer (Centre de Microdensitométrie, Orsay). Some statistical data on the quality of the measurements and the heavy-atom derivatives are given in Table 1. The MIR phases were improved by a solvent modification technique similar to that used by Schevitz et al. 15 in the study of yeast tRNA, Met. The resulting electron density map was easily interpreted for most of the molecule, except in one small region situated in the bottom right part of Fig. 1. A detailed account of the experimental procedures and a complete description of the

Fig. 1 Stereoscopic drawing of the α -carbon backbone of methionyl-tRNA synthetase based on unrefined coordinates measured from the model. The central part (thick line) corresponds to the nucleotide binding domain. The molecule is viewed down the crystallographic b axis.

structure will be given elsewhere. An atomic model (scale 1.25 cm per Å) was built, which accounts for 480 amino acid residues.

There is no complete chemical sequence available for methionyl-tRNA synthetase but its molecular backbone is

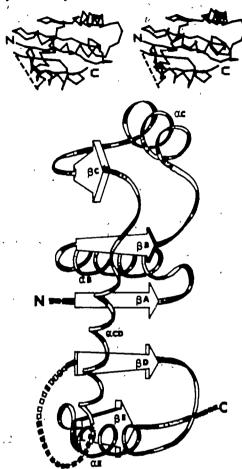

Fig. 2 A stereo view of the nucleotide binding domain in methionyl-tRNA synthetase, together with a schematic representation of its structural elements. The nomenciature of the helices and β strands are those proposed by Hill et al.². The β strands are represented by arrows pointing towards their C-terminus. The dotted chain between helix α CD and strand β D represents that part of the molecule which is depicted at the bottom of Fig. 1 (thin line). The view is approximately down the a^{α} axis. N and C represent the amino and carboxyl ends of the chain, respectively.

shown in Fig. 1. The elongated molecule $(90 \times 52 \times 44 \text{ Å})$ consists of three distinct domains: (1) a central core (thick line in Fig. 1) formed by five parallel strands separated by helices and containing the N-terminus; (2) a less regular structure (thin line at the bottom of Fig. 1) containing ~ 135 amino acid residues, which can be visualized as an intrusion between the third and fourth strands of the central core; and (3) a third domain (thin line, top of Fig. 1) rich in helices, which pears the C-terminus of the polypeptide chain.

The most salient feature of the structure is, by far, the central core, which shows the topological characteristics of a 'nucleotide binding domain': (1) it is composed of a five-stranded parallel pleated sheet with helices connecting the strands. (2) The sequential order of the strands, as shown in Fig. 2 is, from top to bottom, $\beta C - \beta B - \beta A - \beta D - \beta E$. (3) Helices αB and αC are 'below' the pleated sheet (Fig. 2) while helices α CD and α E are 'above' it. (4) The nucleotide 8-bromo-ATP, which was used as a heavy-atom marker, binds near the C-terminal end of the pleated sheet (in our interpretation this binding involves contacts with the loop between strand βA and helix αB and with side-chains of helix aB). These features clearly indicate a remarkable structural homology with the nucleotide binding domain of dehydrogenases. Note that although the structure of tyrosyl-tRNA synthetase from Bacillus stearothermophilus seemed at first to bear no structural relationship to other proteins¹⁶, an improved model revealed the existence of a Rossmann fold around the ATP binding site 17.

Methionyl-tRNA synthetase is thus a new member of the family of proteins which possess the characteristic Rossmann fold. This supports the hypothesis that many nucleotide binding proteins may derive from a common ancestral gene 18,19. By gene fusion and duplication, this gene would have evolved in a divergent evolutionary process to give rise to the modern dehydrogenases and aminoacyl-tRNA synthetases (the situation is less clear for kinases which show a rather wide variety of topologies in their ATP-binding domain). The nucleotide binding domain of methionyi-tRNA synthetase, however, has a unique feature, that is, the helix α CD and the strand β D are far apart in the sequence (they are separated by ~ 135 residues). These residues build a domain (bottom of Fig. 1) whose structure bears little resemblance to a Rossmann fold. This extra domain could be the result of the insertion of a segment of DNA into the ancestral gene²⁰. Conversely, aminoacyl-tRNA synthetases could mirror the existence of a longer ancestral gene which, after deletions, would now code for the nucleotide binding domains in the dehydrogeneses. Interestingly, the presence of an extra domain has also been reported for pyruvate kinase (PK)¹¹ as compared with triose phosphate isomerase (TIM)²¹. The two enzymes show a characteristic barrel of eight

Statistical data on the quality of intensity measurements and heavy-atom derivatives, given as a function of resolution. N is the number of phased reflections. Due to the geometry of the oscillation method, about half of the reflections are measured more than once; the R_{sym} factor $(R_{\text{sym}} = \sum |< F| > -F|/\sum F|)$ gives a measure of the agreement between symmetry-related reflections. P is the phasing power of the heavy-atom derivatives, that is, the ratio of the r.m.s. heavy-atom scattering to the r.m.s. lack of closure: $P = [\sum f_b^2/n]^{1/2}/[\sum (F_{\text{ph}}^{\text{obs}} - F_{\text{ph}}^{\text{obs}})^2/n]^{1/2}$. The derivatives used were obtained with $\mathbb{K}_2\text{Pt}(\text{CN})_4$, $\mathbb{K}_3\text{UO}_2F_5$, $\text{Sm}(\text{NO}_3)_3$ and 8-bromo-ATP (8-Br-ATP). The last derivative was used only at 4 Å resolution. m, Figure of merit. For each derivative (including the parent) $\sim 20\%$ of the measured reflections were rejected (too weak or poor R_{sym}).

parallel strands connected by helices which is continuous in TIM, and in PK contains ~100 additional residues, inserted between the third strand and the third helix.

Knowledge of the complete amino acid sequence for methionyl-tRNA synthetase may hopefully provide further insight into its taxonomic relationships with other nucleotidebinding proteins.

We thank J. P. Waller, who initiated this work; S. Blanquet, G. Fayat and P. Dessen for stimulating discussions and gifts of enzyme preparations; V. Luzzati for his continued interest; D. M. Blow for computer programs; J. Bluteau for the design of Fig. 2 and the MRC Laboratory of Molecular Biology, Cambridge for some of the computer programs used in processing. This work was supported in part by a grant from the DGRST.

Cationic control of O₂ affinity in lugworm erythrocruorin

Roy E. Weber

Institute of Biology, University of Odense, DK 5230 Odense M. Denmark

The erythrocruorins (extracellular haemoglobins from annelids¹) have molecular weights of 3-4×10⁶, contain 60-192 O2-binding haem moieties per molecule and are much more complex than the tetrameric vertebrate haemoglobins1-However, they perform the same function, carrying O2 from the respiratory surfaces to the tissues, and exhibit similar cooperativity in O2 binding and inhibitory heterotropic interactions between O2- and proton-binding sites (Bohr effects), although these functions show greater adaptive variation than in the vertebrate pigments^{2,3}. Whereas erythrocruorin- O_2 affinity is insensitive to the anionic organic phosphate cofactors like glycerate-2,3-bisphosphate and ATP1-3, which depress the O2 affinity of vertebrate haemoglobin inside the red blood cells, it is increased by inorganic salts⁶⁻⁸. This effect is important physiologically because annelids lack significant capacity for osmotic regulation and experience large fluctuations in blood electrolyte levels8,9. I show here that, in contrast to the situation in man, where anionic cofactors and protons decrease haemoglobin-O2 affinity by specifically depressing the O2 association equilibrium constant of the pigment in the deoxygenated state 10-13 inorganic cations govern the O_2 affinity of erythrocruorin from the burrowing, intertidal lugworm, Arenicola marina, by preferentially modifying the association constant of the (almost fully) oxygenated form. In contrast to the vertebrate mechanism, which optimizes O2 unloading in the tissues, this alternative control mechanism in erythrocruorin seems to be adaptive to O2 loading at the low O_2 tensions generally characteristic of the microenvironments of erythrocruorin-bearing annelids¹⁻³.

Figure 1 shows that NaCl increases O2 affinity and cooperativity (measured as n_{max} , the maximum slopes of the Hill plots) of Arenicola erythrocruorin by increasing the association constant for binding the last O2 molecules, without significantly affecting that for binding the first molecules to the deoxygenated pigment. These constants, which are respectively referred to as K_R and $K_{\rm T}$, by analogy with the R and T states of vertebrate haemoglobin, without implying the existence of only two discrete conformational states, are estimated by lines drawn asymptotic to the experimental curves at extreme high and low O₂ saturations (see Fig. 1). Divalent cations exert greater effect than monovalent ones at the same anion concentration and also slightly increase K_T (Fig. 1). These results imply preferential cation binding to erythrocruorin in the oxygenated form and provide a rare example of an heterotropic effector that increases O2 affinity in haem pigments.

The differential effects of salts on K_T and K_R raise the free energy of haem-haem interaction, ΔG (which equals RT In (K_R/K_T) where R is the gas constant and T the absolute temperature¹⁴). At pH 7.37, which approximates the in vivo value at 15 °C (refs 1, 2), the K_R/K_T ratio indicates a 33-fold higher affinity for the last compared with the first O2 molecules bound, and a ΔG value near 8.4 kJ mol⁻¹ in the absence of salts. The presence of 0.6 M Na⁺ or 0.12 M Mg²⁺ (which approximate the blood levels in lugworms from normal seawater¹²) raises K_R/K_T to ~68 and ΔG to ~10.0 kJ mol⁻¹ (Fig. 1, right The mechanism of ionic interaction in erythrocruorin is radically different from that in human haemoglobin, where glycerate-2,3-bisphosphate lowers $K_{\rm T}$ (reducing the association constants for the first three but not the last O2 molecule) and where neutral salt acts in a qualitatively similar manner except that it also slightly increases K_R (refs 10-12). Both control mechanisms, however, have the same net effects, increasing ΔG

Proton concentration also acts mainly on K_R of erythrocruorin but in the opposite direction to salt concentrations, shifting the oxy-asymptote to lower affinities and reducing ΔG and n_{max} (Fig. 2). This also contrasts with human haemoglobin, where lower pH reduces K_T and only slightly affects K_R , raising ΔG and cooperativity¹³. The present data allow estimation of the Bohr effects for binding of the first and last O_2 molecules (Δ $\log K_T/\Delta pH$ and $\Delta \log K_R/\Delta pH$, respectively) as -0.20 and -0.74, showing that most protons are released on binding of the last O2 molecules.

The shifts in the oxy-asymptotes of Arenicola erythrocruorin imply the existence of different R states whose O2 affinities depend on cation and proton binding. Ions thus affect not only the apparent equilibrium constant for the transition between the deoxy- and oxy-forms but also the non-exclusive binding coefficient $c(=K_T/K_R)$, in contradiction of the two-state $model^{15}$ as defined for human haemoglobin, where c is invariant of the concentration of the allosteric effector.

The fact that the ion sensitivity of erythrocruorin resides with $K_{\rm R}$, rather than with $K_{\rm T}$ as in human haemoglobin, seems to be adaptive to O2 transport in hypoxic (O2-poor) conditions in the natural habitat of annelid worms. In contrast to air-breathing animals where loading O2 tensions generally are sufficient to saturate the pigment fully, so that O2 transport can only be improved by increasing O2 unloading, O2 transport in hypoxic microenvironments depends on O_2 loading and thus K_R . In animals like Arenicola, a salt-induced increase in K_R and thus in n_{max} and O_2 affinity will favour oxygenation of the erthrocruorin in the gills during tidal emersion, when severe burrow hypoxia 16 coincides with high blood salt levels as a result of saline, dense, high-tide water remaining in the burrows8. Again, the proton sensitivity of KR, resulting in a greater Bohr effect at high degrees of O₂ saturation, will augment the O₂ affinity difference between blood at relatively high O2 tension and pH (as in the gills) and blood at lower O₂ tension and pH (as in tissues)¹⁷. As the published data show that in nature tissue O2 tensions in Arenicola marina fall sufficiently to unload the pigment at low tide16 and that gill-tissue pH differences do occur18, the salt and

Left: Is 0.17 mM; Y is the tractional O₂ saturation. Left: Hill plots in the absence of cation (♠) and in the presence of 0.12 M NaCl (○), 0.25 M NaCl (●), 0.62 M NaCl (□) and 0.12 M MgCl₂ (♠). Right: effects of NaCl (♠) and MgCl₂ (♠) on the association equilibrium constant for the first and last O₂ molecules bound (K_T and K_R, respectively) and on the free energy of hearm-harm interaction. AG. The cert energy of haem-haem interaction, ΔG . The erythrocruorin, collected as described previously, was stripped of ions by passage through mixed ion-exchange resin (Amberlite MB-3) and dialysis against distilled water. Cation concentrations were varied by the addition of solutions of analytical grade cationchloride salts and controlled by chloride measurement using a Radiometer CMT-10 titrator. The O₂ equilibria were measured with a diffusion chamber technique 19,20 except that the stepwise increases in O₂ tensions were generated by cascaded gas mixing pumps (Wösthoff) while absorbance changes between zero and full saturation (when equilibrated with pure N2 and O2, respectively) were monitored on recorders with high sensitivity (Radiometer REA 112) units. Extremely low and high saturations were measured by amplifying absorbance increments near zero and full O₂ saturation in separate runs, observing previously described precautions¹¹. The asymptotes were fitted by eye. With the upper asymptotes the saturation points were additionally estimated from extrapolations in plots of $\Delta \hat{V}$ against 1/p. (cel. 12) The tions in plots of ΔY against $1/p_{\rm O_2}$ (ref. 13). The application of small amounts of erythrocruorin solutions (layer thickness $\sim 10~\mu \rm m$) minimized equilibration time and meterythrocruorin formation, which was always less than 1% and corrected for graphically²⁰.

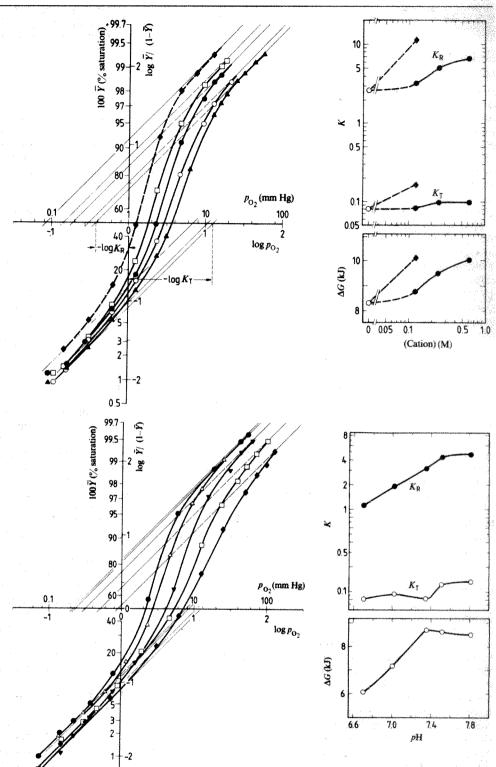

Fig. 2 Effects of pH on O₂ equilibria of Arenicola erythrocruorin, measured in 0.05 M HEPES-NaOH buffer at 15 °C. pH values (left panel): 7.81 (♠), 7.51 (♠), 7.35 (♥), 7.02 (□) and 6.70 (♠). The cor-Tris buffers (compare ▼ with ▲ in Fig. 1) indicates the absence of significant buffer effects. Other details are as for Fig. 1.

proton interactions will increase the capacity of the blood for transporting O₂.

MATTERS ARISING

Rebuttal of criticisms of remote viewing experiments

MARKS¹ has argued that our first two remote viewing (RV) studies (with subjects Price and Hammid)² should be discounted as evidence for the RV hypothesis. He claims that sensory cues in the subject-generated RV transcripts provide sufficient information to permit judges to blind-match transcripts to target sites on an artefactual basis. The evidence, however, does not support this claim.

First, with regard to the Hammid series. When one examines the details of Marks' criticism (see ref. 3) one finds that the criticism about cueing is based on an error-in-fact on the part of Marks; he erroneously assumed that the target list given to judges was in the order of target usage, that is, unrandomized. That is incorrect. That list, which Marks used to formulate his criticism, was randomized by random number generator to prevent the very possibilities he raises. When this fact is taken into account, one finds that his criticism is voided at its foundation. Specifically, his criticism is derived from the fact that the transcripts were dated; however, the dates do not provide the useful cue information posited by Marks-they would have done so only under the (incorrect) assumptions about target order made by Marks. As a result. Marks' attempt to associate the transcripts to the target sites on the basis of the alleged cues failed.

With regard to the Price series. While not questioning the data collection procedures or commenting on the near-photographic accuracy of some of the individual descriptions, Marks and Kammann hypothesized in their first critique that the successful judging of the Price series might be due to sensory cues in the transcripts that provide information as to, for example, whether a given trial was early or late in the series4. In response to this we arranged to have the series independently rejudged, using transcripts from which the suggested cues had been removed. The rejudging resulted in the same seven out of nine target/transcript matchings as in the original study, indicating that it was the quality of the transcripts themselves, rather than the presence of cues, that was responsible for the successful outcome². This rejudging is rejected by Marks because of the potential confounding factor of the publication of the original studv.

This leads us to a second re-analysis of the Price series for which, in order to give the Marks' hypothesis its best chance, we assume all potential cues remain and are used to maximum advantage; we then rigorously assess the consequences. In the strongest case for cues the probability of a correct match can at most be increased from one-ninth to one-third; in another

case from one-ninth to one-seventh; and in two other cases from one-ninth to oneeighth. The remaining five cases gain no direct advantage from cues, just indirect advantage from not using as possibilities the ones already used in the more advantageous cases. When one takes into account the resulting constraints due to cues, the number of possible target/transcript matchings is reduced from 9!= 362,880 to 68,760 combinations, by exact count. Assuming that the cues are used to maximum advantage, we find that the significance level associated with obtaining at least seven matches in nine trials (as was done) in a forced-choice, nonindependent assignment of transcripts to target sites (the most conservative statistic) is only reduced from $P = 10^{-4}$ to P = 3.9×10^{-4} , still a quite significant result. (A paper containing the details of this analysis has been published elsewhere⁵.) Thus, the Marks hypothesis that the presence of extraneous cues accounts for the significance of the Price series result receives no support.

We would summarize by first indicating that we recognize that our original RV studies are not without flaw, and the potential effect of possible cues deserves critical examination. However, in our continuing re-examination of this work we find that the suggested cueing artefacts, although providing some potential for confounding, are yet well below the magnitude necessary to account for the strength of the results. As a result, this re-examination of the data has provided yet additional support for the hypothesis indicating the existence of a human remote sensing capability. This conclusion is supported by the continuing replication of RV experiments in our own and other laboratories^{6,7} for which the Marks concerns no longer apply due to the increased sophistication of the procedures in use.

Expression of herpesvirusinduced antigens in human cervical cancer

DREESMAN ET AL. have described the expression of two herpes simplex virus type 2 (HSV-2) antigens, designated ICSP

11/12 and ICSP 34/35, in 38% of cervical tissues with pathological findings of severe dysplasia or carcinoma. Their undocumented statement that previous studies used antisera against HSV virions and gave rise to equivocal results is inaccurate and generates controversy where none exists. Indeed, the expression of HSV-2 antigens in cervical anaplastic tissue has been consistently and unequivocally demonstrated using antisera prepared against extracts of HSV-2-infected cells that contain both structural and nonstructural viral proteins. To our knowledge, there is no report describing the failure to identify HSV-2 antigens in cervical anaplastic tissue when such have been studied. Had the authors' comment on the equivocal nature of previous results been valid, their data demonstrating the presence of two antigens, the viral identity of which may be questionable to some critics, in only 38% of patients with anaplastic findings could hardly support their conclusion that HSV-2 is a factor in human cervical cancer1.

Using antisera against total viral antigens, HSV-2 antigens were demonstrated by immunodiffusion and crossed immunoelectrophoresis in extracts of cervical tumour cells²⁻⁴. Similarly prepared antisera were used by Athanasiu et al.5 in immunofluorescent staining of frozen sections of cervical tumour biopsies. Expression of HSV-2 antigens was described in 8 of 24 (33.3%) specimens from cervical carcinoma, a percentage remarkably similar to that described by Dreesman et al. , using similar specimens. The observation that viral antigens are preferentially expressed in cells on the peripheral part of the carcinoma mass towards the vagina and/or cervical canal^{6,7} has led some investigators to conclude that the proportion of reactive patients could be greatly increased by studying the cervical cells that have naturally exfoliated or have been induced to exfoliate artificially. Immunoflorescent staining of such specimens with antisera against total viral antigens in six independent studies⁶⁻¹¹ has demonstrated the expression of HSV-2 antigens in cells of 61-81.2% of patients with dysplasia and 92-100% of those with invasive cancer or carcinoma in situ (CIS). This compares with a reactivity of 0-9.4% in normal women (Table 1).

We showed previously that antisera against an antigenic fraction designated AG-e, that consists of two viral proteins (ICP 12, ICP 14)¹², stains cervical anaplastic cells from patients with dysplasia, CIS or invasive cancer, but not from normal women¹⁰. Consistent with this finding, antisera against ICP 12 or ICP 14 also stain the cells from patients with these pathological findings¹¹. It is significant that ICP 12 shares a number of

Table 1 % Of patients exfoliated cells staining with antisera to viral antigens*

Diagnosis	Total†	AG-e‡	ICP 12	ICP 14
Normal (N)	0-9.4	0	0	0
Dysplasia (D)	61-81.2	69-72.6	57	51
CIS and invasive (Inv)	91.6-100	91.4	100	75

* Athanasiu et al. 5: 33.3% of frozen sections of cervical carcinoma stained with antiserum to total viral antigens. Normal tissue was negative.

† Pacsa et al.⁸: N = 9.4%, D = 61%, CIS/Inv = 94%. Adelusi et al.⁹: N = 0, Inv = 100%. Minhui et al. 6 : N = 9%, Inv = 100%. Aurelian et al. $^{7.10}$: N = 0, D = 81.2%, CIS/Inv = 91.6%. 4 Smith et al. 11 : N = 0, D = 72.6%, CIS/Inv = 91.4%. Aurelian et al. 10 : N = 0, D = 67.6%, CIS/Inv = 86.4%.

properties with Dreesman's ICSP 11/12—the two proteins have the same molecular weight and both bind DNA^{1,13} Antisera against them stain the nuclei of HSV-2-infected cells, but staining of cervical anaplastic cells is cytoplasmic and perinuclear f.11

We suggest that the findings of Dreesman and his colleagues cannot be considered in isolation of previous evidence in this field. They neither offer conceptually new information, nor do they help elucidate a hitherto equivocal or controversial issue. The significance of their findings lies specifically in their confirmatory nature. Only in this context can the authors' conclusion be accepted, that HSV-2 is a factor in cervical carcinoma.

POWELL ET AL. REPLY-We have no intention of generating controversy as Smith, Gupta and Aurelian have suggested. Our aim was to examine sections of cervical tissue biopsy specimens for the presence of two specific HSV antigens. We detected both proteins in about onethird of the samples of abnormal tissues¹. As we detected the HSV antigens in the unstressed biopsy specimens, this result clearly differs from that of Aurelian et al.2, in their paper "HSV-2 antigens absent from biopsied cervical tumor cells: a model consistent with latency" wherein

they were unable to demonstrate the presence of HSV-2 antigens in cervical tumour biopsies from 29 patients. We would agree that all published reports have found at times expression of HSV antigens in exfoliated cervical cells.

Previous results are equivocal. Thus whilst Athanasiu et al.3 reported the presence of virus antigens in cervical tumour biopsy specimens using antisera to crude virus antigens and the indirect immunofluorescence test, this result was not obtained by Nahmias et al.4, Aurelian et al.2 or by ourselves1. Even in studies of exfoliated cells, reports differ as to the presence of virus antigens in cells from normal patients or from patients with bland disorders and in the proportion of patients with overt disease showing positive reactions with antisera to crude virus protein mixtures^{2,5,6}. It is important not to gloss over such differences as they may be highly significant.

Our approach was quite different from that of previous reports. We selected two proteins ICSP 11, 12 and ICSP 34, 35 because they are both DNA-binding proteins. Both are known to be virus specific and have been mapped using intertypic recombinants to specific regions of the viral genome. They were purified to homogeneity and only then used to prepare antisera. The sera were tested to ensure that they only reacted with the polypeptide used for immunization. These reagents obviously differ considerably from the crude or partially purified antigen preparations used by other groups to prepare antisera for previous studies^{2,4-6}. With these reagents two independent studies have detected expression of HSV antigens in about onethird of cervical tumour biopsies^{1,7}. We were totally unable to detect HSV antigens in the same specimens using potent general antisera to total virus proteins, in contrast to results reported by Aurelian's group with exfoliated cervical cells (60-90% of dysplasic CIS/invasive cancer patients samples positive even using antisera to crude infected cell extracts).

Finally, we are amazed at the casual way in which Smith, Gupta and Aurelian associate their ICP 12 and ICP 14 (which they have clearly shown to be structural proteins capable of inducing neutralizing antibody⁸) with ICSP 11, 12 which is a non-structural protein totally absent from even the worst preparations of purified virus. Our reagents and our results are clearly different from those of Aurelian and her co-workers.

Recent thrusting in the Appalachians

STUDIES of incremental strain have been used in an attempt to understand recent tectonism in regions, such as eastern North America, which are generally considered to be tectonically inactive. Yet one of the best pieces of evidence of recent tectonism and incremental strain is seismicity, and eastern North America has historically been seismically quite active1.

Schäfer² has studied apparent recent tectonism in the Appalachians using offset drill holes to indicate incremental strain. Incremental strain is observed in drill holes following construction of presplit highway cuts in the Cumberland-Allegheny Plateau, and in the western Valley and Ridge of Tennessee, West Virginia and Pennsylvania.

We have examined three of the four localities described by Schäfer, and other localities nearby. Our additional data suggest that tectonic stresses resulting in faulting are responsible for the observed offsets but that there is no evidence of post-palaeozoic tectonism.

Examination of exposures along Interstate Highways 40 and 75 in Tennessee and at Oak Flat, West Virginia, revealed numerous offset drill holes in Pennsylvanian and Devonian sandstone (and sandstone/shale). All observations were confined to near-vertical presplit roadcuts in which the rocks are minimally weathered providing less chance of error caused by measurements on loose blocks.

In all offset holes containing multiple offsets, or in any succession of offsets from

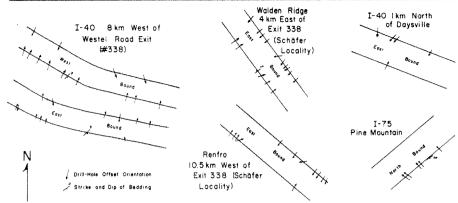

Fig. 1 Orientations of displacement for drill holes at the localities in Tennessee.

the base to the top of a cut in the Tennessee localities, the amount of offset increases upwards. Also, in most drill holes in which there are multiple offsets, the offset vectors are nearly parallel. Where offset vectors are not parallel, differences in motion may generally be explained by relative rotation of one of the upper blocks during blasting, later slumping, readjustment across major joints, or some other local process. At the West Virginia locality south-west of Oak Flat, the sense of movement is reversed from the base to the top of the cut on the north side of the highway. On a lower-to intermediate-level fracture the drill holes are offset away from the highway, whereas on an upper-level fracture the offset vectors have moved towards the highway.

A consistent relationship between offset vectors and highway cut orientation was noted. Orientation vectors are consistently oriented approximately normal to highway cuts. Most vectors symmetrically converge towards the centre of the highway (Fig. 1). At one locality in Tennessee, measurements were made in two parallel cuts of westbound and eastbound lanes separated by 30-50 m of rock. Offset vectors converge symmetrically towards the centre of the westbound lane, but vectors on both the north and south sides of the eastbound lane point north (Fig. 1). Using an elastic rebound mechanism, this pattern may be explained by excavation of the westbound lane first, initiating rebound and release of elastic strain energy throughout the mass. The differential in total or average offset of drill holes from the westbound to the eastbound lane (consistently greater effects in the westbound lane) favours a difference in time of excavation for the two lanes.

Offsets may cease to exist from one side of prominent joints (properly oriented) to another. One side of a joint may be offset as much as 30 cm whereas drill holes on the other side of the joint may be offset only 0 to <2 cm.

Stresses which produce observed strains, such as offset drill holes, may be simply interpreted as having a tectonic origin². However, relatively high near-surface in situ stresses may also originate from non-tectonic processes³.

Static loads derived from the weight of rock material composing a topographic high may become resolved into shearing stresses directed along properly oriented existing planar discontinuities, such as subhorizontal bedding. As long as these stresses are less than the shearing strengths of the rocks involved or less than the stresses necessary to reactivate existing planar discontinuities, no permanent strain would result. There would also be some dependence of storage of elastic strain energy on the elastic moduli of the rock mass. The most favourable orientations for static load-derived shearing stresses to be relieved would obviously be those which would permit movement outwards from the source of stress. A downward-directed static load may be relieved effectively by horizontal motion, provided this otherwise normal stress may be transformed into shearing stresses (Fig. 2). Existing subhorizontal planar discontinuities (bedding or fractures) may provide shear surfaces along which the stresses may be relieved. Motion along these surfaces may be accelerated during blasting where rapidly expanding gases are forced along bedding or fracture surfaces. The gases separate the rock mass and effectively lubricate it to overcome the coefficient of internal friction along the surfaces, so that accumulated elastic strain energy is released. Further strain may be caused by subsequent creep along discontinuities.

Blocks which are surrounded by properly oriented joints may contain no stored energy. Joints generally dip 70° or more. Those which are sufficiently open (not locked) and are oriented at low to moderate angles to the outward-directed shearing stresses may be relieved without offsetting drill holes.

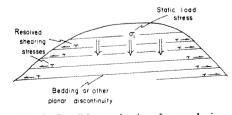

Fig. 2 Possible mechanism for producing subhorizontal shearing stresses from a nontectonic source.

We conclude that offset drill holes are a common phenomenon in the Cumberland-Allegheny Plateau of Tennessee and West Virginia where bedding is nearly horizontal. Drill holes are offset by release of stored elastic strain energy produced by static load. Offset drill holes in the Cumberland-Allegheny Plateau and in the Valley and Ridge are not related to recent tectonism. All tectonic structures present here predate highway construction and are probably Palaeozoic structures.

- Schaeffer, M. F., Steffens, R. E. & Hatcher, R. D. Jr. Southeastern Geol. 20, 129 (1979).

SCHÄFER REPLIES—Hatcher and Webb have observed additional offsets of drill-holes with vectors oriented normal or oblique to the highway cuts. I agree that many of these displacements result from the release of static load-derived strain which is a common feature in the Appalachians and in other mountainous areas.

hatcher and Webb stated that I simply interpreted those offsets as having a tectonic origin. However, I did not consider any offset vector which was directed towards or away from a highway, although a tectonic component could also be involved. Offset vectors oriented parallel to the highway cuts were not included, either, in myanalysis when the excavation of the raod was directed radially to a topographic high. As of sites 1 and 2 at Interstate highway 40, Tennessee. which is NW-SE-oriented, a topographic high is located north-east of the highway. Also at the West Virginia site the highway cut runs tangentially to a topogkraphic high in the north-west. Thus, it is not surprising that Hatcher and Webb observed numerous drillholes with offset vectors normal or oblique to the road cuts. Other non-tectonic offset vectors may even run in the direction of the road-cut when static load-derived tangential tensile stresses induce dip-slip movements.

The borehole offsets which I considered, however, are all parallel (in one case sub-parallel) to the highway cuts revealing considerable rock masses to be upthrusted by tectonic forces and not by blasting. The tectonic origin of these faults evidently is not doubted by Hatcher and Webb as they did not mention any of these borehold offsets in their discussion.

New Journal!

Agroforestry Systems

(vol. 1/4 issues, 1982)

Published in cooperation with ICRAF

Editors: Dr. H.J. von Maydell, Institut für Weltforstwirtschaft, 2050 Hamburg 80, Leuschnerstr. 91, P.F. 80 02 10, Hamburg, F.R.G. (Chairman); Prof. Dr. G. Budowski, Centro Agronomico Tropical de Investigacion y Enseñanza, Turrialba, Costa Rica; Dr. B. Lundgren, Director-International Council for Research in Agro-Forestry, P.O. Box 30677, Nairobi, Kenya; Dr. H.A. Steppler, McGill University, Faculty of Agriculture, Ste. Anne de Bellevue, Quebec H9X 1C0, Canada.

Subscription price: dfl. 125,— plus dfl. 23,— for postage and handling. Private subscription price available upon request.

Agroforestry Systems is an international, multidisciplinary journal which will provide a rapid publication outlet for all types of research concerned with the various aspects of agroforestry systems, and for critical reviews on all sustainable land management systems which combine agriculture, animal husbandry, and trees on the same unit of land.

Agroforestry Systems has the following objectives:

- to identify techniques, methods, policies, education and training suitable for rural development in the various ecological regions of the world, predominantly in the tropics;
- to supply the decision maker at all levels on progress, constraints and advantages of multidisciplinary land use planning;
- to contribute in solving dominant problems of rural development by stimulating demand oriented applied science.

Topics to be covered:

Special emphasis will be given to fundamental and applied research and to practical experiences on

- Contributions of agroforestry to solving problems of rural development
- Agro-sylvo-pastoral systems and ecosystems
- The rôle of trees in agriculture, range and livestock management, horticulture and multiple land use
- Compatibility of agricultural, pastoral, horticultural and multiple land use practices with forest management
- Shifting cultivation and related practices
- Tree-based farming and multi-purpose tree products
- Economics of agroforestry, monitoring and evaluation
- Acceptability of new policies and techniques to rural societies.

It is hoped this publication will encourage cooperation and mutual exchange of knowledge between the different disciplines involved in land use. A forum is offered for open discussion.

Call for papers

Authors who wish to contribute to Agroforestry Systems are invited to send manuscripts or requests for 'Instructions to Authors' to the Editorial Office Agroforestry Systems, P.O. Box 566, 2501 CN THE HAGUE, The Netherlands.

Orders should be sent to your regular supplier or to:

Enzymes as Drugs

edited by J.S. Holcenberg, Children's Cancer Center and Medical College Wisconsin,

and J. Roberts, Memorial Sloan-Kettering Cancer Center, New York

The diverse applications of enzymes as therapeutic agents are reviewed here, and the book discusses methods used to alter enzymes to overcome problems of biodegradation, distribution and antigenicity by chemical modification, encapsulation and binding of the enzyme to surfaces.

July 1981 0471 05061 X 466 pages \$79.20/£41.50

Protein - Protein Interactions

edited by **C. Frieden,** Washington University of Medicine, St. Louis,

and L.W. Nichol, Australian National University, Canberra

Discusses the interactions between proteins and between subunits within a single protein, as well as the methodology involved in the study of those interactions. It draws from such diverse fields as immunology, enzymology, subunit-subunit interactions and ligand binding to acceptor molecules, and self-assembly of rod-like protein structures. It includes the theory and methodology for mass migration behaviour (sedimentation and chromatography), fluorescence energy transfer, light scattering, x-ray crystallography, and other physical techniques.

June 1981 0471 04979 4 416 pages \$66.45/£33.45

Topics in Bioelectrochemistry and Bioenergetics, Vol. 4

edited by **G. Milazzo,** Istituto di Chimica della Facolta di Ingegneria, Universita di Roma, Italy

This series gathers together reviews of topics concerned with energy transduction and electrochemical processes in biological systems, and techniques for their investigation. The volumes of the series will include discussions of fundamental biochemical mechanisms of such processes as phosphorylation, photosynthesis, electron and ion transport, various metabolic redox reactions, membrane phenomena, certain pharmacological and pharmacodynamical properties, and transmission of information at cellular level.

June 1981 0471 27904 8 356 pages \$90.00/£35.00

Methods of Biochemical Analysis, Vol. 27

edited by D. Glick, Standford University, California

The volumes in this series are designed to try to meet the needs in the field of biochemical analysis. The topics to be included are chemical, physical, microbiological, and if necessary, animal assays, as well as basic techniques and instrumentation for the determination of enzymes, vitamins, hormones, lipids, carbohydrates, proteins and their products, minerals, antimetabolites, etc.

July 1981 0471 06503 X 548 pages \$56.50/£29.75

Analysis of Pesticide Residues

edited by H. Anson Moye, University of Florida

A comprehensive guide to the latest techniques and applications of pesticide trace analysis. Methods covered include gas, thin layer, and high-performance liquid chromatography, along with their applications in the analysis of chlorinated hydrocarbons, acidic herbicides, organophosphates, carbamates, and insect pheromones and hormones. Includes a special chapter on residue data requirements of government agencies.

Chemical Analysis Series, Volume 58

March 1981 0471 05461 5 478 pages \$56.25/£29.65

The Biochemistry of Silage

by **P. McDonald,** University of Edinburgh and Edinburgh School of Agriculture

An understanding of the basic biological principles underlying the preservation of crops as silage is essential before we can modify the conservation process in order to obtain a more nutritionally desirable product. This book is an attempt to review in detail the biochemistry of silage fermentation, although a sufficiently broad approach has been used to include other factors of biological importance such as the effects of various additives on fermentation and the nutritional value of different types of silages.

July 1981 0471 27965 X 226 pages \$42.00/£16.00

Semiochemicals:

Their Role in Pest Control

edited by **D.A. Nordlund,** Southern Grain Insects Research Laboratory;

R.L. Jones, University of Minnesota,

and W.J. Lewis, Southern Grain Insect Research Laboratory

Presents material on all aspects of semiochemicals, with extensive coverage of kairomones, synomones, allomones, and apneumones as well as pheromones. It describes the involvement of the various semiochemicals in the different types of interactions between insects of the same species, of different species, and with other organisms in their environment, It also discusses the involvement of many physical stimuli and their importance in some interactions.

July 1981 0471 05803 3 328 pages \$48.00/£25.20

Principles and Practices of Rice Production

by S.K. De Datta, Department of Agronomy, The International Rice Research Institute, The Philippines

Topics include: the importance of rice; environments; the chemistry of submerged rice soils; growth and development stages; varietal development and seed production; systems of cultivation and management of land, water, soil fertility, and fertilizer; various pernicious agents (rodents, insects, etc.); the technology of harvesting; and the biological and socioeconomic barriers to high yields.

BOOK REVIEWS

Time to change

T. W. Marshall

THIS, book deserves to be read, and discussed, at several different levels, and not all levels can be covered in a single short review. The chemist or physicist who wishes to understand Prigogine's concept of "dissipative structure", and its application to systems far from thermodynamic equilibrium, for which he received the Nobel prize for chemistry in 1977, will find in Part II — "The Physics of Becoming" - a clear explanation of where both equilibrium and linear non-equilibrium thermodynamics become inadequate, and of how an externally imposed inhomogeneity, such as a temperature gradient, produces a new kind of order. Examples are given from physics (convection in the atmosphere), chemistry (periodic chemical reactions) and biology (cell accretion).

As its title implies, the book is more than that. Prigogine's Nobel award citation referred to his "bridging the gap between biological and social fields of enquiry", and he sets out here to share his insights with a wider reading public. His central character is Time, and he states the problem in his preface: to relate three different concepts of time occurring in dynamics (time as a simple parameter with no preferred direction), thermodynamics (time has direction, but leads inescapably towards "heat death") and biology (time as evolution and, ultimately, history).

In the preface, Prigogine acknowledges a debt to past giants in the field, Ludwig Boltzmann and Jacques Monod. In this work and its companion volume (La Nouvelle Alliance, written jointly with Isabelle Stengers and published by Gallimard in 1979), he makes a strong bid to join them.

But he is no philosophical soulmate of these two. Both describe themselves unhesitatingly as materialist in outlook, and Prigogine recounts how Monod rebuffed his attempt to establish common ground, classifying his programme for unifying the physical and social worlds as a variety of animism. Possibly this somewhat intemperate rejection led Prigogine, in his turn, to misunderstand Monod. For he quotes the passage from Chance and Necessity about man being "a stranger in the world from which he evolved by accident" as though Monod was referring to life as the strange feature. A more careful reading reveals that the strange feature, peculiar to our species, is consciousness - that which leads us

From Being to Becoming: Time and Complexity in the Physical Sciences. By Ilya Prigogine. Pp.272. ISBN hbk 0-7167-1107-9; ISBN pbk 0-7167-1108-7. (W. H. Freeman: 1980.) Hbk \$24.95, £16.70; pbk \$12.95, £7.95.

ultimately to scientific and philosophical enquiry about our environment. So if, as Prigogine proposes, we need a "second time" to describe irreversible processes, including life, how can he be sure that we do not need a "third time" to describe consciousness?

It is to Boltzmann, however, that Prigogine mainly addresses this work. He begins by noting, like Boltzmann and Gibbs before him, that in a purely dynamical system, based on a hamiltonian evolution function, it is not possible to construct a state function having the time-directional property of entropy. The "Poincare-Misra theorem" (Chapter 7) simply puts this long-known result into the modern terminology of Lyapunov functions. Yet every thermodynamic system has an entropy. Ask a physical chemist and he will measure it for you. Hence the problem.

Gibbs's solution, which Prigogine rejects, was to say that the irreversibility of thermodynamic processes is an illusion, a creation of the physical chemist's imagination. Prigogine quotes some fragments of the Einstein-Besso correspondence which suggest that Einstein also held this view. But a closer examination of those letters, especially the passages dealing with Brownian motion, shows that, in fact, Einstein supported Boltzmann.

Boltzmann's solution was to propose that, in addition to the dynamical laws of evolution of a large system, we should require the initial state to be one of "molecular chaos". He anticipated Prigogine's diagram 7.3 and asserted that, since a state with all the molecular velocities reversed does not have this property, it will almost never occur in any actual physical system.

Prigogine, applying some new results obtained by mathematicians working in ergodic theory, thinks he has *derived* Boltzmann's molecular chaos from the dynamics. But has he? I believe not

That is not to deny that he and his coworkers have achieved a great deal. They have shown, more clearly than most, that Boltzmann's definition of chaos has to be extended to include higher order correlations in the motions of neighbouring molecules. And, for certain simple timeevolving systems, of which the most discussed is the non-dynamical Baker's transformation, they show how to construct an entropy operator which is compatible with the evolution operator. But the very fact that they end up with an entropy operator shows that they, like Boltzmann, are considering not a single microstate, but a set of states on which only certain averages are specified. To specify a probability measure on this set is to impose a more sophisticated molecular chaos hypothesis. So Boltzmann, rather than Prigogine, invented the concept of "second time"

In his remarks on Einstein's refusal to accept quantum mechanics, Prigogine is really out of his depth. It is the case that some quantum theorists are now proposing to abandon the 400-year-old notion of space going from Galileo through Einstein. on which all science since the Renaissance is based, preferring a "biological" space in which a change in one place produces instantaneous changes everywhere else. Such a feature, called "non-locality" seems to be an unavoidable consequence of quantum theory, and Einstein drew our attention to it nearly 50 years ago. But, in his enthusiasm for biological models, based on such phenomena as the cooperative motion of the parts of a chicken embryo, Prigogine thinks he sees common ground with the elementary particle 'zoologists' in their high-energy physics laboratories. This is unwise, because the non-locality some physicists speak of has never been observed, and quite possibly it never will be. On the other hand, the nonlocality exhibited by a chicken embryo certainly does not require superluminal signals to sustain it. It is easily subsumed within a materialist world-picture of the type supported by Boltzmann and Einstein. This is especially the case once full account is taken of the field concept. something which Prigogine almost totally ignores — Faraday does not rate a mention, and Maxwell enters only through his contribution to kinetic theory.

This is not a great book, and Prigogine has not yet achieved what Boltzmann did in *Populäre Schriften* or Einstein in *The World As I See It*. But it is a very good book, and the ideas contained within it promise better things to come.

T. W. Marshall is a Lecturer in Mathematics at the University of Manchester.

What's new in the mechanisms of enzyme regulation?

Edwin G. Krebs

Protein Phosphorylation in Regulation: Recently Discovered Systems of Enzyme Regulation by Reversible Phosphorylation. Vol. 1 of Molecular Aspects of Cellular Regulation. Edited by P. Cohen. Pp.273. ISBN 0-444-80226-6. (Elsevier/ North-Holland Biomedical: 1980.) \$63.50, Dfl. 130.

As the title of this first volume in a series on cellular regulation suggests, the emphasis is on new systems that for the most part have not been reviewed extensively heretofore. The editor of the series, Philip Cohen, who is one of the world's foremost authorities on protein phosphorylation, provides an introductory chapter that gives an excellent summary of the well-established role of this process in the regulation of glycogen metabolism. His succinct account will provide readers with a broad outline of the history and evolution of the general principles of protein phosphorylation, but at the same time will not burden them with an enormous load of information that is available elsewhere. A more exhaustive treatment of glycogen metabolism in this book would have detracted from the reviews that follow. These include chapters by different authors on pyruvate kinase, acetyl CoA carboxylase, hydroxymethylglutaryl CoA reductase, steroidogenesis, triacylglycerol synthesis, muscle contraction, protein synthesis, the phosphorylation of ribosomal proteins and the phosphorylation of histone H1. Parenthetically, it should be noted that the word "enzymes" is used in a very loose sense in this volume, in that the topics covered include the phosphorylation of proteins ordinarily not thought of as enzymes.

The individual contributions, which, with one exception, are clear and well written, follow a general theme developed in the introductory chapter. Brief descriptions of the more classical enzymology of a given system, including non-covalent regulation, are followed by the more recent work concerned with phosphorylation-dephosphorylation. The latter, which constitutes the principal thrust of each article, is generally handled by progressing from in vitro phosphorylation to the more difficult in vivo situations. Most of the authors make an effort to apply criteria of physiological relevance to the phosphorylation phenomena that have been observed. This aspect is especially well handled in sections on the regulation of pyruvate kinase, the control of protein synthesis and the modification of histone H1. A final chapter in the book, again written by Cohen, highlights common features of the various phosphorylation systems and forecasts future directions that will be taken by workers in this field; in addition,

he introduces an interesting hypothesis concerning the mechanism of action of insulin in the regulation of protein phosphorylation.

The book can be recommended for readers who desire timely, concise reviews of work on various aspects of metabolic regulation controlled by protein kinases and phosphoprotein phosphatases. It is

designed more for the non-specialist than for the specialist, but anyone reading the volume will profit from the experience, particularly if he reads it in its entirety.

Edwin G. Krebs is a Senior Investigator at the Howard Hughes Medical Institute and Chairman of the Department of Pharmacology, University of Washington, Seattle.

Newtonian style and scientific revolution

Richard S. Westfall

The Newtonian Revolution, with Illustrations of the Transformation of Scientific Ideas. By I.B. Cohen. Pp.414. ISBN 0-521-22964-2. (Cambridge University Press: 1981.) £18, \$37.50.

TWENTY-five years ago, Professor Cohen's influential Franklin and Newton (American Philosophical Society, 1956) established him as the foremost student of Newtonian natural philosophy. Over the intervening years a constant stream of publications has at once expanded our understanding of Newton and the scientific revolution and maintained Cohen's position. To that stream he now adds another major volume, The Newtonian Revolution, the revised text of the Wiles Lectures delivered at the Queen's University of Belfast. As the two-part title suggests, the book divides into two major sections, one on the Newtonian revolution in science, the other on the doctrine of transformations as an interpretive explanation of the development of scientific ideas. Though the book contains several lengthy asides which are connected only tenuously to the central argument, the two sections maintain a fundamental unity by focusing on the same developments in Newtonian science. In Cohen's view — a view that most historians of science would enthusiastically endorse — the elaboration of the Principia was the single most important step forward in the course of modern science. The appearance of Professor Cohen's detailed analysis of it constitutes a major event in the historiography of science.

While the title of Part I recalls Thomas Kuhn's Structure of Scientific Revolutions, it is Part II, Transformations of Scientific Ideas, which speaks directly to the issues Kuhn raised. Where Kuhn argued for discontinuities in the growth of science, revolutions characterized by sudden switches in the perception of nature, Cohen stresses continuity in which every revolution is achieved by the transformation of received concepts. He is presently at work on a general exposition of

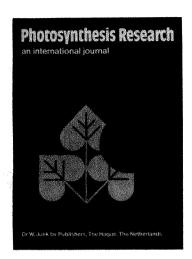

his theory of scientific growth. In the present volume he illustrates it by examining the same events that are central to his understanding of the Newtonian revolution. For the latter he develops the important concept of the Newtonian style by which he seeks both to identify the essence of Newton's contribution and to characterize the nature of modern science. Central to the Newtonian style is the use of mathematical constructs which successive modifications make ever more adequate to the full complexity of physical reality. Equally important is the postponement of enquiry into causes until maximum agreement between the construct and the world of experience has been attained. The idea of the Newtonian style enables Cohen to distinguish Newton's approach from that of other quantifiers and geometrizers in seventeenth century science. No one insisted more on the role of geometry in natural philosophy than Kepler, but, as Cohen shows, Kepler started with causal hypotheses and arrived at mathematical constructs, whereas the Newtonian style proceeded in the opposite order. The primacy of causal hypotheses likewise separated Newton from his continental critics, who were not inconsiderable mathematicians. As I indicated, the concept of a Newtonian style in science, which Cohen argues persuasively was a more important ingredient in his enduring influence than the specific content of the Principia, strikes me as a major contribution to our growing understanding of the scientific revolution.

I feel bound to add that, in my opinion, there are problems attached to this exposition of the concept. Professor Cohen has confounded what philosophers call the context of discovery with the context of justification and has insisted, almost perversely, in using a concept adapted to the context of justification to expound Newton's process of discovery. Few scientists have been less autobiographical in their publications than Newton. He was on the one hand an extremely introverted man who was always concerned to keep his

New Journals!

Photosynthesis Research

(vol. 3/4 issues, 1982)

Editor-in-chief: Dr. R. Marcelle, Laboratory of Plant Physiology, Research Station of Gorsem, Brede Akker 3, B-3800 Sint Truiden, Belgium.

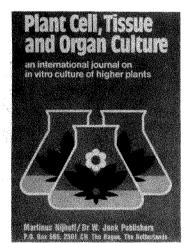

Subscription price: dfl. 140,— plus dfl. 23,— for postage and handling. Private subscription price available upon request.

Photosynthesis Research aims to provide a forum for original papers dealing with photosynthesis without imposing an artificial division between fundamental and applied research. Our aim is to cover all aspects of photosynthesis research starting from the primary reactions and going as far as the energy from biomass. Topics acceptable for publication could include primary reactions, electron transport, photophosphorylation, carbon assimilation, regulatory phenomena, environmental and ecological aspects of photosynthesis, photorespiration, CO₂ fixation in CAM plants, and bacterial and algal photosynthesis, although one should not feel restricted just to these topics.

In the case of artificial systems, the authors should be able to judge for themselves whether to publish in a photosynthesis or photobiology journal. In the case of doubt, the Editorial Board can help the author in making this decision.

Papers will be considered for publication at all levels of plant organization: sub-cellular, cellular, whole plant and canopy levels.

Manuscripts submitted for publication are always reviewed by two referees, not necessarily members of the Editorial Board, and chosen for their competence in the field covered by the paper. The appeal to people who are not members of the Editorial Board is necessary in order to cover the whole field of photosynthesis.

Plant Cell, Tissue and Organ Culture

(vol. 2/4 issues, 1982)

Editor-in-chief: Dr. D.K. Dougall, W. Alton Jones Cell Science Center, Old Barn Road, Lake Placid, New York 12946, USA.

Subscription price: dfl. 130,— plus dfl. 23,— for postage and handling. Private subscription price available upon request.

This is a new quarterly journal that will publish original results of studies on the various aspects of the in vitro culture of higher plants — including fundamental methodological and technical aspects. The contents include growth and development, technical aspects, anatomical, histological and ultrastructural aspects, physiology and biochemistry, genetics and breeding, phytopathological aspects and biotechnology.

New Journals!

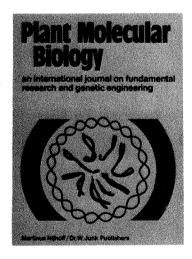

Plant Growth Regulation

(vol. 2/4 issues, 1982)

Editor-in-chief: Dr. T.H. Thomas, National Vegetable Research Station, Wellesbourne, Warwick CV35 9EF, England.

Subscription price: dfl. 130,- plus dfl. 23,- for postage and handling. Private subscription price available upon request.

This journal will offer rapid publication for substantial papers linking fundamental and applied research on the use of natural and chemical regulators as tools for the regulation of growth and development of plants. It should also cover the effects of growth regulating substances in plants and the role of interfering factors. The topics to be covered are: Biosynthesis, translocation and metabolism of hormones, modes of action and interaction of hormones, at cellular and organ levels, development, screening and application of chemosynthetic PGR's. Uptake and translocation of applied PGR's, interactions of bio- and chemosynthetic PGR's, regulation of growth and life cycle: germination, growth, flowering, storage organs, ripening, dormancy, abscission, senescence. Effects of PGR's on water relations, nutrient flow and metabolic processes, genetic control of hormone systems, plant anabolics, control of stress phenomena, control of post-harvest quality, PGR residues and side effects, environmental effects of the use of growth regulators.

Plant Molecular Biology

(vol. 2/4 issues, 1982)

Editor-in-chief: Prof. R.A. Schilperoort, Biochemical Laboratory of Leiden State University, Wassenaarseweg 64, 2333 AL Leiden, The Netherlands.

Subscription price: dfl. 130,- plus dfl. 23,- for postage and handling. Private subscription price available upon request.

This journal will provide an outlet for all types of research concerned and connected with plant molecular biology and genetics. Special emphasis will be given to the following topics: organisation of plant genomes and genes and regulation of their expression at various levels, cloning and sequencing of plant genes, construction of molecular cloning vehicles to be used in plant cells, expression of cloned plant genes, controlling DNA elements, protein bio-synthesis, molecular action of plant hormones, molecular aspects of plant and organelle development, molecular interaction of symbionts, saprophytes and pathogens with plants, molecular biology of nitrogen fixation.

建设设施

distance from others. On the other hand, he held advanced standards of rigour and elegance. More than any other scholar, Professor Cohen himself has taught us to appreciate Newton's immense care in his presentation as he continually revised everything he wrote to express his exact meaning. In the present book, he now asks us to receive these same writings as autobiographical accounts of the process by which Newton arrived at his conclusions. Paradoxically, this leads Cohen wholly to reject the validity of genuine autobiographical statements which appear in some of Newton's manuscripts. No doubt the statements were usually self-serving. At best they must be handled with caution, and perhaps some or even all of them need in the end to be dismissed entirely. Surely, however, it is not the published form of non-autobiographical works that can determine what to accept and what to reject.

Cohen's approach leads him to insist that, because Newton expressed reservations, he never seriously entertained the existence of particulate forces in matter and that, because he stated in the Principia that gravitational attraction may be performed by impulse, he always believed that the final explanation of gravity would involve a material aether. Cohen's own theory of the Newtonian style applied to the context of justification puts this material in quite a different light. With a remarkably cold eye, Newton distinguished demonstration from speculation, even when the speculation contained some of his most cherished convictions. He chose not to mix mere belief, no matter how deeply held, with what he took to be demonstrations. When we approach his work from this angle, the very concept of a Newtonian style leads us to an account of the development of Newtonian science that is quite different from the one Professor Cohen presents. In my opinion, it is a more convincing account. We see a Newton who was the boldest speculator of the century, a man who was able to break out of the confines of received natural philosophy and to put questions no one else could formulate. The Newtonian style, the separation of speculative explanatory hypotheses from mathematically demonstrated regularities in nature, controlled the speculation by proposing what he could not demonstrate under titles such as "Oueries".

Thus I like the notion of a Newtonian style; it gives definite form to important characteristics of Newton that have hitherto not been clearly perceived and articulated. At the same time, I remain to be convinced that the Newtonian style is a useful instrument in the elucidation of Newton's own scientific development.

Richard S. Westfall is Professor of History and Philosophy of Science at Indiana University, Bloomington, and author of Never at Rest: A Biography of Isaac Newton (Cambridge University Press, 1981).

Minerals through the microscope

R.A. Howie

Optical Mineralogy: The Nonopaque Minerals. By Wm Revell Phillips and Dana T. Griffen. Pp.677. ISBN 0-7167-1129-X. (W.H. Freeman: 1981.) £24.60, \$39.95.

ALTHOUGH this book was originally intended to be the companion volume to Mineral Optics: Principles and Techniques (1972), to supply the necessary tables of properties and mineral descriptions, it developed into a more comprehensive work. There are two quite distinct parts: Part I contains detailed descriptions of most varieties of the common rockforming mineral groups, while Part II presents an "abbreviated summary" (pp.399-665) of the optical properties of "all" non-opaque mineral species (including some first described as recently as 1979). The optical descriptions are illustrated with orientation sketches and determinative graphs of optical properties against composition, though unfortunately refractive indices are given as n_a , n_{ε} etc. rather than as α , ε as recommended by the International Mineralogical Association. For a small proportion of the minerals there are diagrams of the crystal structure, but although the compositional ranges are discussed there are no phase diagrams at all (even for the Al, SiO, system of the plagioclase series). Notes on zoning, alteration, distinguishing features and occurrence are included, together with a few selected references.

In addition to summaries of the optical and physical constants of the non-opaque minerals, Part II also gives the typical habit, colour (in thin-section and in hand specimen), alteration and occurrence, together with remarks (solubility, group, polymorph etc.) and one reference. The authors state in their preface that it is hoped that this volume will be accepted as the logical successor to A.N. Winchell's

Science and the President. Pergamon Press have recently issued in paperback Science Advice to the President, a volume tackling many of the same questions raised by Harvey Brooks in his review of Science at the White House by E.J. Burger (Nature 290, 634). The book is a collection of 23 essays by all but one of the past Science Advisers and by other well-qualified individuals, edited by William T. Golden. Prices are hbk £25, \$50; pbk £5, \$9.95.

British Anthozoa. In his review of British Anthozoa (Nature 291, 520) Sir Maurice Yonge regretted the absence of colour illustrations from the book. R.L. Manuel has compiled another guide to anthozoans which contains colour photographs of all but three of the British species. The book was published last year by the Underwater Conservation Society and is available from UCS Sales, 148 College St. Long Eaton, Nottingham NG10 4GX, price £16.

Elements of Optical Mineralogy, II: Descriptions of Minerals (Wiley, 1951) and Larsen and Berman's The Microscopic Determination of the Nonopaque Minerals (US Geological Survey, 1934), both long out of date and out of print. Comparison might also be made with Kostov's Mineralogy (author's translation edited by P.G. Embrey and J. Phemister), published by Oliver & Boyd in 1968. Certainly, Part II of the present work will prove invaluable. With the rapid discovery of new minerals (currently at the rate of around 80 each year) no single work can ever contain all critical data on all non-opaque minerals. but mineralogists will be in debt to Phillips and Griffen for some years.

In Part I, the detailed descriptions of the commoner rock-forming minerals are wellpresented, yet surely are not quite detailed enough. Comparison is inevitably to be made with Battey's Mineralogy for Students (Oliver & Boyd, 1972) or Deer, Howie and Zussman's Introduction to the Rock-Forming Minerals (Longmans, Green, 1966). Admittedly the present work is concerned with optical mineralogy, but it does include sections on the occurrence of the various minerals and these are not always sufficient for a petrologically inclined mineralogist, e.g. for the garnet group. Nor are the references particularly up-to-date - the most recent augite reference is to a 1970 paper, and for biotite, 1966, though perhaps this is merely a reflection of the increasing use of X-ray and electron microprobe techniques in preference to those of optical mineralogy. The amphibole sections take no account of the IMA rulings (1978) for the nomenclature of this group. Nevertheless this descriptive part of the book is well-produced and attractively presented with numerous clear diagrams and quite a few microphotographed pairs (taken with plain-polarized light and with crossed polars). It must be said, however, that after the colour photographs in MacKenzie and Guilford's recent Atlas of Rock-forming Minerals in Thin Section (Longman, 1980), these black-andwhite photographs seem uninspiring.

Perhaps the biggest surprise about this book is the juxtaposition of the two parts which would seem to cater for rather different levels of readership. The listing of properties of all known non-opaque minerals in Part II will appeal to final-year honours students and particularly to research workers at all levels, whereas the mineral descriptions in Part I would, in my opinion, be insufficient for a final year honours course in geology. It is, however, remarkably good value at under £20; all libraries catering for the earth sciences should have it.

R.A. Howie is Professor of Mineralogy at King's College, University of London.

Hennig in English: hypotheses for entomology's systematists

R. A. Crowson

Insect Phylogeny, By W. Hennig. Translated and adapted by A. C. Pont, with revisionary notes by D. Schlee. Pp.514. ISBN 0-471-27848-3. (Wiley: 1981.) £28, \$84.

WILLI Hennig's 1969 volume, Die Phylogenie der Insekten (published by Waldemar Kramer), while undoubtedly a work of scholarly importance, received rather less than due attention in the English-speaking world. At the time of his death in 1976, Hennig was accumulating notes for a revised English-language version of the work. In its lieu, the present volume provides a translation of the 1969 text into good and readable English, interspersed with Hennig's surviving notes for a revision, and supplementary notes by younger, mainly German entomologists designed to bring into consideration work

published since 1968. The bibliography now includes some references as recent as

The "methodological introduction" summarizes Hennig's phylogenetic methods, more fully set out in his Phylogenetic Systematics (University of Illinois Press, 1966). It is followed by a review of Palaeozoic and Mesozoic fossil data on insects, a systematic account of the phylogenetic relations of modern insects down to about order or suborder level, and a more detailed review of the phylogenetic relations of Mesozoic insects. Illustrations are mainly dendrograms or pictures of wings; the bibliography is extensive though far from exhaustive.

The main phylogenetic conclusions, not significantly changed by the later annotations, agree largely with those of Boudreaux's Arthropod Phylogeny with Special Reference to Insecta (Wiley, 1979) who also applied Hennigian methods, though Hennig goes into more detail. A notable feature is the use of a numerical system denoting taxa, based on Hennig's belief that phyletic splittings are almost always binary, these numbers being directly convertible into a topologically correct dendrogram. One effect of the binary system is the use of a large number of classificatory levels — thus it takes eight splittings to get from Insecta (= Hexapoda) to an order such as Diptera, though only two to Diplura.

Perhaps the most important of the additions are due to Dieter Schlee, who brings into consideration a good deal of recently described fossil evidence, not known to Hennig in 1969. Otherwise, the later annotators seem mainly concerned with promulgating their own views about particular orders, not always in a very scholarly manner. Some of these writers, and even Hennig himself, may at times be accused of unduly dogmatic assertion thus Hennig states that the theory of a blood-sucking ancestor for Diptera "is certainly not correct"; Mickoleit writes "There is no longer any doubt that the Mecoptera are a monophyletic group"; and Kinzelbach states flatly that "Strepsiptera have no evident gula". Hennig himself, and M. Baehr, are both guilty of misunderstanding and misrepresenting my own views on the Coleoptera at some points.

For the non-entomological systematist, the work should be of interest as the example of Hennig's own application of his method to higher-level classification of a major section of the animal kingdom. The data used in this work are drawn almost entirely from the fields of classical comparative anatomy and palaeontology; its conclusions should be taken as scientific hypotheses, which could be tested against evidence from fields such "macromolecular systematics" not taken into account by Hennig and his co-

It is to be regretted that neither Hennig nor his annotators have tried seriously to establish ancestral modes of life for the taxa with which they are concerned. The result is that the book has little of interest to the new, rising school of palaeoecologists, or even to palaeogeographers, despite Hennig's own interest in geographical distribution as evidence for phylogeny. The main users of the book will undoubtedly be entomologists and palaeoentomologists, for whom this well produced volume should be a desirable acquisition.

Forms of magnetic behaviour

B. R. Coles

Introduction to the Magnetic Properties of Solids. By A.S. Chakravarty. Pp.696. ISBN 0-471-07737-2. (Wiley: 1981.) £35,

MAGNETISM continues to present challenges to our physical insight and abilities to produce firmly based formal theories. With its wide range of phenomena and richness in relevant concepts (spin, exchange, spin-waves, domains, ferromagnetism, spin density waves, crystal fields and so on), it is a much more difficult subject to present to the student in an orderly fashion than, on the one hand, classical electricity and magnetism or, on the other, quantum mechanics. Faced with this dilemma authors either accept the complexity and diversity of the real world of the magnetic properties of matter or turn their back on it until they have laid the formal theoretical foundations which they are convinced will ultimately be the basis of explanations of the behaviour of all magnetic matter. As this book (which is firmly in the second category) shows, the difficulty of the latter approach is that the materials and properties described tend less to be those of intrinsic interest than those that illustrate the bits of theory that can be tackled fairly rigorously. It contains very few figures showing the behaviour of real materials (the first is on p.150 and the second on p.265) and those are chosen solely to compare with rather specific calculations rather than because of their power to illustrate important effects.

For the theoretical physicist who seeks

interesting problems that give promise of possible solutions with existing techniques. this will be a helpful introduction that moulds his thinking along the lines that have been thoroughly explored and found useful. It does not, however, give the introduction promised in the title to the magnetic properties of real solids in all their diversity or even to some modern theoretical developments. Some omissions are understandable, given the tenor of the book, but it is strange to find a transition from an account of the band theory of solids to theories of itinerant ferromagnetism - which oddly fails to refer the student to Herring's classic text (Magnetism edited by G. Rado and H. Suhl, Vol IV; Academic Press, 1972) with no reference to the susceptibilities of metals that do not become magnetically ordered. The treatment of spin-wave spectra is surprisingly brief and there is no discussion of the powers of neutron scattering in their investigation. There is also no discussion of the phase transition aspects of magnetism which are currently a focus of much theoretical effort -"critical phenomena" and "renormalization group" do not appear in the index. It is a pity that space that might have introduced even these theoretical aspects was taken up with extended treatments of standard background theoretical formalism which are easily found elsewhere.

B. R. Coles is Professor of Solid State Physics at Imperial College, University of London.

R. A. Crowson is a Senior Lecturer in the Zoology Department at the University of Glasgow.

UNIVERSITY OF DURHAM

DEPARTMENT OF CHEMISTRY Applications are invited for a

LECTURESHIP IN **CHEMISTRY**

tenable in the Department of Chemistry from 1st January, 1982. The successful candidate will be

expected to fulfil all the normal duties of a University lecturer and teaching responsibilities will primarily be in Organic Chemistry. It is anticipated that the person's research interest will be complementary to those of staff in the department and preference will be given to candidates with an interest in Plasma Synthesis and/or Surface Aspects of the Organic Solid State.

Salary on the scale £6,070 £12,860 with superannuation benefit.

Applications (3 copies) naming three referees should be sent by September 11th to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from further particulars are available (9121)A

OXFORD UNIVERSITY PRESS

EDITORIAL ASSISTANT (Science)

for A Supplement to the OED A vacancy has arisen in Oxford for an Editorial Assistant on the staff of the Supplement to the Oxford English Dictionary, researching and writing entries, for scientific terms in the fourth volume (Se-Z).

Applicants should have a good degree in a life science and some further relevant experience. A historical sense, a broad interest in scientific terminology and the use of English, and some reading knowledge of German are desirable.

The appointment will be for a fixed term of four years, with a salary on the scale £4,515 to £6,715 according to age and experience.

Application should be made in handwriting to John Swanzy, Personnel Department, Oxford University Press (Publishing), Walton Street, Oxford OX2 6DP, with a full curriculum vitae and the names and addresses of two referees. (9172)A

THE UNIVERSITY OF AUCKLAND New Zealand

GEOGRAPHY -**LECTURESHIPS**

Applicants should have research and teaching interest within one or more of the following fields: Human Geography, especially Social or Economic Geography; Physical Geography, especially Biogeography; Remote Sensing, Resource Management.

Commencing salaries will be determined in accordance with qualifications and experience. Present salary scales are: Lecturers, NZ\$19,140 - \$23,520;

Conditions of Appointment and Method of Application are available from the Assistant Registrar (Academic Appointments), University of Auckland, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications in accordance with 'Method of Application' should be forwarded as soon as possible but not later than the closing date stated.

Closing Date: 2 October 1981.

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS

POSTDOCTORAL-SENIOR RESEARCH ASSISTANT

Applications are invited for a Approximations are invited for a postdoctoral Senior Research Assistant supported by the Merseyside Regional Health Authority and the British Heart Foundation, to investigate the mechanisms of action of vitamin K and anticoagulants. A knowledge of high performance liquid chromatography techniques would be advantageous, but not essential. Candidates should possess a higher degree in chemistry, biochemistry, pharmacology or related subjects.

The appointment is for two years, commencing 1 October, 1981, at an initial salary of £6,070 per annum with USS Benefits.

Applications (two copies), together with the names of three referees should be received as soon as possible, to The Registrar, The University, PO Box 147, Liverpool L69 3BX. Quote Re. RV/852

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE

(University of London) DEPARTMENT OF

NEUROLOGICAL SCIENCE

SENIOR TECHNICIAN

required to operate fluorescenceactivated cell sorter, working in a research group studying the immunology of myasthenia gravis and related disorders. Experience in relevant physics, instrumentation or cellular immunology preferred. Ref: JTT/ST

TECHNICIAN

required for raising monoclonal auto-antibodies, working in a research group studying the immunology of myasthenia gravis and related disorders. Experience of cell culture essential. Ref: JTT/T

Both posts available for 5 years from October 1st 1981, based at the Royal Free Hospital, Hampstead. Salaries on appropriate Whitley Council Scale. Application forms are available from the School Secretary, Royal Free Hospital School of Medicine, 8 Hunter Street, London WCIN 1BP. (01-837 5385 ext 54). Please quote appropriate reference. Closing date 31 August 1981.

(9170)A

British Museum (Natural History) Electron Microscopist

. . . to join a team involved in taxonomic research covering the whole field of natural science. Work includes preparing material for both scanning and transmission microseopy; monitorin quality and recording results; first line maintenance of microscopes and high vacuum units and maintenance of a small library. Candidates normally under 27, should have a degree in

biological sciences. Experience as a technician in an electron microscope unit would be advantageous.

Appointment as Scientific Officer £5,825 - £7,495 (salaries under review) with starting salary according to qualifications and experience. For futher details and

application form (to be returned by 31 July 1981) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please quote ref: SB/69/DK.

Monsanto

a large organization with European Headquarters in Brussels and Research facilities in pleasant surroundings at Louvain-la-Neuve, 30 km South of Brussels, is expanding its Agriculture Research Programs in the field of plant growth regulators.

The Biological Evaluation section intends to make new appointments for

SCIENTISTS

with the ability to carry out and direct fundamental and applied research projects. These projects will be related to the discovery and development of plant growth regulators for use in major arable crops.

Applicants should have a PhD in plant science or agronomy, a strong background of plant/crop physiology, preferably 2 years of experience in applied crop research and a proven ability to supervise research teamwork.

Candidates should apply in writing to Personnel Department, Monsanto Technical Center, rue Laid Burniat, B-1348 Louvain-La-Neuve, Belgium.

Monsanto

of higher education

SCHOOL OF NATURAL SCIENCES
RESEARCH DIVISION
KELSTERTON COLLEGE, CONNAH'S QUAY, DEESIDE, CLWYD.

RESEARCH SCIENTIST

IN PHOTOCHEMISTRY AND RADIATION CHEMISTRY

This is an established research position within the School of Natural Sciences, which undertakes considerable work with industrial collaborators. Applicants should have a research degree and initiative and must be familiar with the techniques of pulse radiolysis and nanosecond laser flash photolysis.

Salary within the range of £5,034 to £8,658 with promotion to higher grades possible if the appointee is successful. Further details and application forms are available from the Institute Registrar, The Coach House, Kelsterton Road, Flint, Clwyd. Telephone Deeside 816236. Closing date for receipt of applications 31st July 1981. (9136)A

SENIOR PROFESSORSHIP IN INORGANIC CHEMISTRY

Professor, University of Florida, inorganic chemistry, with an active program in internationally recognized inorganic chemical research. Teaching duties may include undergraduate and graduate level inorganic courses. Top-level salary with major departmental research support.

Preferred starting date: August, 1982. Direct inquiries or applications to Professor Harry H Sisler, Chairperson of Search Committee, Department of Chemistry, University of Florida, Gainesville, FL 32611.

Applications should include complete curriculum vitae, bibliographies of publications, indication of on-going and probable future research interests, and a list of three or more references who will be asked to supply letters of recommendatin (a university personnel requirement). The University of Florida is an Affirmative Action/Equal Employment Opportunity Employer. Application deadline: November 15, 1981. (NW766)A

THE UNIVERSITY OF AUCKLAND New Zealand

SCHOOL OF MEDICINE
CHEMICAL PATHOLOGY —
ASSOCIATE-

PROFESSORSHIP OR SENIOR LECTURESHIP

Candidates must hold a medical qualification registrable in New Zealand, together with a recognised postgraduate qualification in Pathology (for example FRCPA or MRC Path). The successful applicant will be involved in the undergraduate and postgraduate teaching courses in Pathology, and will be expected to pursue actively research projects relevant to interests. The person appointed will be attached to, or in charge of, the Chemical Pathology Laboratory Service at Auckland Hospital.

Commencing salaries for medically qualified staff will be established in accordance with qualifications and experience:

Associate-Professors: At present salaries for Associate-Professors are established within the range NZ\$42,817 — \$48,286 per annum.

Senior Lecturers: NZ\$32,162 x 7 annual increments to \$40,258 per annum. Senior Lecturers may be paid an appropriate allowance for clinical responsibilities.

Conditions of Appointment and Method of Application are available from the Assistant Registrar (Academic Appointments), University of Auckland, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications, in accordance with 'Method of Application', should be forwarded as soon as possible but not later than 30 September 1981.

(9154)A

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF BIOCHEMISTRY

RESEARCH FELLOWSHIP

Applications are invited for a Research Fellow to work with Dr S J Ferguson on an SERC project entitled "Structural and Mechanistic Studies on Proton Translocating ATPases". The main emphasis will be on identifying and sequencing specific peptides from functionally important parts of the mitochondrial and bacterial enzymes, but some enzymological work is also anticipated. Experience in protein chemistry advantageous although not essential.

The appointment is for three years commencing 1st October 1981 (or as soon as possible thereafter) in the range £6,070 to £10,575. Starting salary not expected to exceed £6,880.

Applications (2 copies), including a curriculum vitae and the names of three academic referees, should be sent by 20th August 1981 to Jane Nelson, Senate Registry, University of Birmingham, PO Box 363, Birmingham B15 2TT, from whom further details may be obtained.

(9158)E

Molecular Biologist/Biochemist

Sittingbourne, Kent

Shell Research Limited has a vacancy for a post-graduate molecular biologist/biochemist to join a multidisciplinary group investigating the nature of chemical carcinogenesis and developing novel techniques for predicting carcinogenicity. The major challenge of the job will be to apply modern techniques of molecular biology, particularly recombinant DNA methodology, to solve toxicological problems.

The candidate we are looking for will be a first class experimentalist, aged up to 30 years, who possesses an excellent grasp of modern concepts of the structure, function and regulation of DNA.

The Research Centre has modern, well-equipped laboratories situated on a 450 acre farmland site near Sittingbourne. We offer a competitive salary and assistance will be given with relocation expenses where appropriate. You will be able to join our pension fund and other benefits include a subsidised staff restaurant and excellent sports and social facilities. Please write or telephone for an application form to:

Shell Research Ltd., Recruitment Division, PNEL/25 (N2), Shell Centre, London, SE1 7NA. Telephone:- 01-934 2948.

UNIVERSITY OF NEWCASTLE UPON TYNE

FACULTY OF AGRICULTURE

RESEARCH ASSOCIATE

Applications are invited for the temporary post of Research Associate in the Department of Agriculture for a period of 2 years to work on a project sponsored by the Opencast Executive of the NCB. The work will be to evaluate and improve the agricultural potential of land restored after opencast coal mining and will involve detailed investigation of grass and cereal root growth in both undisturbed and restored sites. Candidates must have recent research experience in a related area of study.

The appointment will be made at the appropriate point on the scale for research and analogous staff: Range 1A £6,070 — £10,575 according to age, qualifications and experience.

Further particulars may be obtained from the Senior Assistant Registrar (FP), University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne NE1 7RU, with whom applications (3 copies) together with the names and addresses of 3 referees should be lodged not later than 1st September 1981. Please quote reference N.

(9122)A

THE UNIVERSITY OF MELBOURNE CHAIR OF MATHEMATICS

The University of Melbourne invites applications for a Chair of Mathematics, which is one of four chairs in the Department of Mathematics. The Chair recently became vacant following the resignation of Professor Leon Simon to take up a chair in the Institute of Advanced Studies, Australian National University. The appointee will be expected to develop teaching and research in a branch of Mathematics. Applicants in analysis, differential geometry, and topology are particularly sought. It is not intended to appoint a person whose main interests are in the applications of mathematics.

Salary: \$A41,509 per annum.

Further information about the position, application procedure, superannuation, travel and removal expenses, housing assistance and conditions of appointment are available from the Registrar or from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H OPF. All correspondence (marked "Confidential") should be addressed to the Registrar, The University of Melbourne, Parkville, Victoria 3052, Australia

Applications close on 31 October 1981. (9149)A

CONNECTIVE TISSUE BIOCHEMIST

Exceptional opportunity to join the Merck Sharp & Dohme Research Laboratories highly regarded professional staff. We are presently seeking a PhD Biochemist to join a team of Cell Biologists, Immunologists and Biochemists who are studying various aspects of the effector mechanisms of immune-based inflammation with particular emphasis on connective tissue degradation. The successful candidate will be expected to develop and utilize state-of-the-art technology for measurement of connective tissue breakdown and turnover with the aim of developing new animal models of chronic inflammation. A good basic training in Biochemistry with emphasis on connective tissue biology and immunological methods is highly desirable.

Salary and benefits highly competitive. Send résumé to: Susan R. Jenkins, Dept. N., Personnel Manager, Merck & Co., Inc., P.O. Box 2000, Rahway, New Jersey 07065

(NW759)A

THE UNIVERSITY OF GARYOUNIS, THE SOCIALIST PEOPLE'S LIBYAN ARAB JAMAHIRIYA, INVITES APPLICANTS TO TEACH FROM THE BEGINNING OF SEPTEMBER 1981 IN THE FOLLOWING FACULTIES:

Faculty of Science (Benghazi) in the following fields.

Geology Department:

- 1. Geophysics.
- 2. Crystallography.
- 3. Petroleum and Subsurface Geology.
- 4. Field methods and Geological Mapping.

General requirements:

- 1. Applicants should hold a PhD degree or its equivalent from a recognised university.
- 2. Experience in university teaching preferable.
- 3. Teaching is in Arabic or English language.

General information: Basic annual salary:

 Professor
 8640 to 9720 LD

 Associate Professor
 7560 to 9640 LD

 Assistant Professor
 6840 to 7560 LD

 Lecturer
 6240 to 6843 LD

Assistant Lecturer

5265 to 6237 LD

One Libyan Dinar (LD) is equivalent to approximately £1.50 or US 3.33 Dollars. Housing is provided by the University: additionally a furniture allowance of 2 months basic salary is provided for married accompanied staff: single staff will be

accommodated in a furnished flat within the campus.

Research and consultation opportunities are available. Funding individual research projects will be considered. Details furnished upon request. The academic year begins on 1 September 1981. Ranks and salaries commensurate with experience. On termination the staff member will receive a gratuity of two months salary for each completed year of service payable at the end of contract. Round trip air tickets from the place of recruitment to Benghazi are given to the staff member and family (up to four children under 18 years) at the beginning and end of contract. In addition a baggage allowance of up to 25% of the price of the air ticket. Leave travel tickets to the place of recruitment for the staff member and his family are given every year. The University provides free medical treatment.

Applications including resumés should be sent to:

The Secretary of the Popular Committee, Faculty of Science, University of Garyounis, Benghazi, The Socialist People's Libyan Arab Jamahiriya.

(9138)A

Wessex Regional Cytogenetics Unit, General Hospital, Salisbury, Wiltshire

A vacancy exists in the above Unit for a Clinical Cytogeneticist (Senior Scientific Officer).

Applications are invited from candidates with experience in human cytogenetics research and with special interest in developing methods for early diagnosis of neoplasia from serious effusions and solid tumours.

He/she should be able to plan and maintain the research programme of the Unit.

Application forms can be obtained from the District Personnel Officer, Odstock Hospital, Salisbury, Wilts SP2 8BJ.

Further details from Dr M Seabright, Tel: (0722) 6212 ext 669. Closing date for receipt of completed applications 17th August 1981.

SALISBURY Health District_

GLASSHOUSE CROPS' RESEARCH INSTITUTE

requires a
BOTANIST OR
HORTICULTURIST

to join the Hardy Ornamental Nursery Stock Section of the Crop Science Division to work on container production of hardy ornamentals with emphasis on the physical aspects of container growing and/or problems associated with field establishment of plants from containers.

The post is designated Scientific Officer Band II/Higher Scientific Officer Band II and is suitable for person with interest in agrometeorology and environmental physics.

Qualifications: Degree in relevant subject or HNC with appropriate experience for appointment at SO level, and at least 3 years postqualifying experience required for higher grade.

Salary within scale £4,809 to £6,480 (SO), £6,075 to £7,999 (HSO) according to qualifications and experience. Non-contributory superannuation scheme. Annual leave 20 days (SO) or 22 days (HSO).

Application forms and further details from Administrative Assistant, Glasshouse Crops Research Institute, Worthing Road, Rustington, Littlehampton, West Sussex BN16 3PU. Closing date for applications 14 August, 1981.

(9164)A

Applications are invited for two vacancies of Research Demonstrators in the Department of Genetics. Candidates should have or expect shortly to have a PhD and be active in research. For one post, experience in evolutionary genetics, and for the other, experience in microbial genetics

active in research. For one post, experience in evolutionary genetics, and for the other, experience in microbial genetics (especially bacterial plasmids) is desirable. The successful applicants will be involved in laboratory and tutorial teaching.

Research Demonstrators

The appointments which will date from October 1 1981 or as soon as possible thereafter, will be for 1 year in the first instance and will be on a scale up to £6,880 pa together with USS/USDPS benefits.

benefits.
Informal enquiries may be made by telephone to Professor J A Beardmore or Dr J M Parry (0792 205678) but application forms must be obtained from the Personnel Office, University College of Swansea, Singleton Park, Swansea SA2 8PP to which office they should be returned by August 20, 1981. (9169)A

ENZYME MECHANISM Ph.D's

THE INTERNATIONAL PLANT RE-SEARCH INSTITUTE (IPRI) invites applicants for its rapidly expanding programs in advanced molecular genetics. Applicants with significant records of frontier achievements are invited to join a strong team of innovative scientific leaders in the pleasant San Francisco area.

Send résumé with recent publications

OFFICER/HIGHER SCIENTIFIC OFFICER) Scientific Officer/Higher

Scientific Officer is required to join a team of three in the Mass Spectrometry Group to be responsible for the development of techniques in mass spectrometry and related chromatography and microscopy to meet the needs of the Institute's research programme and to provide a central Mass Spectrometry Service to other ARS Institutes and Units.

Qualifications: A 1st or upper second class Honours degree in Physics or Physical Chemistry together with experience of mass spectrometry and HPLC. minimum of 2 years post-qualifying experience will be required for HSO grading and a PhD will be preferred.

Salary: On a scale £4,809 — £6,480 (SO), £6,075 — £7,999 (HSO), Under review. Non-contributory superannuation scheme.

Further particulars application form from the Secretary, Food Research Institute, Colney Lane, Norwich NR4 7UA quoting ref. 80/38. Closing date: 6th August

CSIRO AUSTRALIA

Research Scientist/ **Senior Research Scientist** (Research Fellow)

Division of Forest Research Canberra Act

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,400 employees - 2,500 of whom are research and professional scientists located in Divisions and Sections throughout Australia.

Field: Forest Fire Suppression (Project Aquarius).

General: The Division of Forest Research is concerned with the long term use of Australian forests - both conifer plantations and the native eucalypt forests - for wood production, water supply, wildlife conservation and recreation. The Division will establish a project team to investigate the effectiveness of alternative techniques for suppressing forest fires in Australia. The project will investigage:

- The effectiveness of large air-tankers and fire retardants for suppressing fires of varying intensity.
- The effectiveness of conventional fire fighting techniques under similar conditions.
- A cost/benefit analysis of forest and bush fire suppression in Australia.

The multidisciplinary project team will be expected to carry out extensive field work. It will work with officers of a State Forest Service and scientists from other organizations engaged in contract research on this project.

Duties: As part of a team, design, undertake and evaluate experiments to measure the suppression effectiveness of a large air tankers dropping water and fire retardant chemicals on fires of varying intensities.

Note: Duties will involve prolonged field work of up to three months duration in summer.

Qualifications: A PhD or equivalent research experience in an appropriate area, e.g. forest fire suppression, air tanker operations. Operational experience on fire suppression desirable.

Salary: Research Scientist/Senior Research Scientist (Research Fellow) \$A19,662 - \$A28,564 pa. Outstanding applicants may be considered for appointment at a higher level

Tenure: Three years. Superannuation benefits available.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting reference number A3665 should reach: The Personnel Officer, Australian Scientific Liaison Office. Australia House, Strand, London WC2B 4LA by 28 August 1981. Applications in USA and Canada should be sent to: The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue NW, Washington DC 20036.

Current vacancies in CSIRO appear on PRESTEL page 252903.

CHAIRMAN

DEPARTMENT OF GENETICS

The University of Utah, School of Medicine, Salt Lake City, Utah, invites nominations and applications for the position of Professor and Chairman of the new Department of Genetics. This position requires a person with an outstanding research program in genetics, as well as, administrative and leadership qualities, who will interact with both clinical and basic science faculty. This new department will provide the opportunity and requirement to recruit strong faculty.

The university is an equal opportunity/affirmative action employer, thus applications from women and minorities are encouraged.

Inquiries including a curriculum vitae, should be sent to Dr John A Dixon, Chairman Genetics Search Committee, Department of Surgery, Dixon, Chairman Genetics Search Committee, Department School of Medicine, Salt Lake City, Utah 84132. Closing date (NWX764)A

Hereford Area Public Health Laboratory

Director

Leptospira Reference Unit Principal Grade Microbiologist Salary scale £9,720 — £13,635

The Leptospira Reference Unit, currently located at Colindale London, but planned to transfer to become an integral part of the Hereford Area Public Health Laboratory requires a successor to the present Director who will be retiring in November.

The person appointed will work initially as the Deputy Director at Colindale, and thereafter at Hereford, as Head of the Reference Unit, under the overall direction of the Director of the Hereford Public Health Laboratory Service Laboratory.

The Unit provides a reference and a research centre for work on pathogenic leptospires with emphasis on the diagnosis of leptospiral infection in man and on support for epidemiological investigations. The Microbiologist appointed will be responsible for the development of the Unit's scientific programme and for the day to day management of the diagnostic and reference services.

Candidates for this post should have a relevant higher degree or other qualifications supported by experience of both research and medical microbiology, experience in the field of leptospires whilst desirable is not essential.

Interested candidates who would like to discuss this appointment may do so by arrangement with: The Director of the Service, Dr. J. E. M. Whitehead. Telephone 01-200 1295 extension 35.

Further particulars are obtainable from the Secretary to the Public Health Laboratory Service Board, 61 Colindale Avenue, London NE95EQ to whom applications should be sent stating date of birth, qualifications, experience and published work, and naming three referees. Closing date 14th August 1981.

PHLS Centre for Applied Microbiology and Research Bacterial Metabolism Research Laboratory

Senior Microbiologist

Starting salary £7,674 rising by annual increments to £9,921

Applications are invited from microbiologists with an interest in anaerobic bacteriology and bacterial biochemistry to work on the intestinal bacterial flora in relation to chronic and malignant disease of the gastro-intestinal tract.

For further details of the work involved please contact the Director of the Bacterial Metabolism Research Laboratory, Dr. M. J. Hill (telephone 01-205 6144). The starting date will be November 1st, or earlier, when the laboratory transfers from Central Public Health Laboratory, Colindale, to the Centre for Applied Microbiology and Research, Porton Down.

The post will be for an initial period of 1 year with possibility of further extensions to 3 years.

Basic Grade Microbiologist

Current salary scale £4,839 - £7,110

to work on the intestinal bacterial flora in relation to chronic or malignant intestinal disease. The applicant should have an interest in anaerobic bacteria and in bacterial biochemistry. The laboratory is currently situated at Colindale, London NW9 but will move to the Centre for Applied Microbiology and Research on November 1st 1981.

For further details contact the Director of the Bacterial Metabolism Research Laboratory, Dr. M. J. Hill. Telephone 01-205 6144.

NHS Conditions and terms of employment will apply.

Applications for the above 2 Posts with full curriculum vitae stating date of birth, qualifications, experience and names and addresses of three referees should be made to

Mrs. M. Bushby, Personnel Officer, PHLS
Centre for Applied Microbiology and
Research, Porton Down, Salisbury,
Wiltshire SP QJG. Telephone Idmiston
(0980) 610391. Closing date
14th August 1981.

Public Health

Laboratory Service

Coláiste na hOllscoile Corcaigh University College Cork

IRELAND RESEARCH SCIENTISTS IN MICROBIOLOGY

required to work on the molecular Biology of Nitrogen Fixation in Root Nodule Bacteria

1 Geneticist/Molecular Biologist

preferably with a PhD to work on a project involving the genetic engineering of root nodule bacteria. Capabilities in recombinant DNA technology would be an advantage but is not essential as training will be provided.

2 Microbiologist/Microbial Physiologist

preferably with a PhD degree, to work on the physiology and regulation of CO₂ metabolism in rhizobium. This position is tenable in the first instance for one year with the possibility of renewal for a further year.

These positions are supported by the NBS and available from the 1st October 1981. Salaries will be on the appropriate national scales (IR £6,234 — post-doctoral max, including PRSI) with the point of entry negotiable.

Applications, containing full career details and the names of two referees should be sent as soon as possible to Dr. F. O'Gara, Microbiology Department, University College, Cork, Ireland. from whom further particulars are available. (9128)A

UNIVERSITY OF MELBOURNE

DEPARTMENT OF ZOOLOGY

RESEARCH FELLOW GRADE 1

(Extendible Tenure)

Applications are invited from biologists with expertise in the study of zooplankton. The appointee will be expected to study plankton from southern Australian and Antarctic waters in collaboration with staff of the Departments of Zoology and Botany. The appointee will be expected to give a small amount of teaching in undergraduate courses and will be encouraged to supervise postgraduate students. A research interest in trophic relationships or secondary productivity will be preferred. The position is available from 1 January 1982 for a period of up to three years.

Salary within the range \$A17,083 to \$A19,570 per annum.

Further details on the position are available from Professor G D Campbell, in the University.

Further information, including details of application procedure and conditions of appointment, are available from the Staff Officer, University of Melbourne, Parkville, 3052, Victoria, Australia, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close on 30 September 1981. (9116)A

TUMOR IMMUNOLOGY PRE/POSTDOCTORAL

position available immediately. Monoclonal Ab, characterization for human tumor Ag.

Send CV, three ref to: Dr Daniel Eskinazi, USC, PO Box 77912, GER 323, Los Angeles, CA 90007 EOE/MFH (NW765)A

THE UNIVERSITY OF BIRMINGHAM Faculty of Medicine and Dentistry

DEPARTMENT OF CARDIOVASCULAR MEDICINE Applications are invited for the post of

RESEARCH FELLOW

to work on a study of the biochemical role of myosin isoenzymes in the human heart during development and cardiovascular disease. The successful applicant will join the Molecular Cardiology Unit within the department which is investigating the contractile and regulatory proteins in normal and diseased myocardium.

The post, supported by MRC is available up to 30.9.83. Starting salary £6,070 to £6,880 with superannuation.

Further information from Dr P Cummins, Cardiovascular Medicine, Queen Elizabeth Hospital, 021-472 1311.

Applications (three copies) to Assistant Registrar, Medical School, Birmingham B15 2TJ by 15th August 1981. (9157)A

Coláiste na hOllscoile Corcaigh University College Cork

RESEARCH ASSISTANTSHIP GENETICS OF LACTIC STREPTOCOCCI

Applications are invited for a

RESEARCH ASSISTANTSHIP

(supported by the national Board for Science and Technology) to develop a transformation system in the lactic streptococci. Applicants should preferably have a PhD degree and research experience in genetics/ microbiology. The appointment is initially for one year from 1st October 1981 and is renewable.

Salary scale:

PhD degree,

IRE5,370 — IRE5,798; IRE4,417 — IRE5,073.

MSc degree.

Applications with Curriculum Vitae and names and a addresses of two referees should be sent as soon as possible to Dr. C. Daly, Dairy and Food Microbiology Dept., University College, Cork, Ireland.

POST DOCTORAL -RESEARCH POSITION

for Biochemist-Cell Biologist available September 1, for two to three years, to identify, isolate and characterize insulin-like growth factor and α -thrombin receptors. (J. Biol. Chem. Vol 256: 2767, 1981) from cultured cells and tissues.

Experience in membrane protein chemistry, monoclonal antibody production, and/or ligand receptor characterization is desirable but not essential. \$15,000 to \$20,000 yearly depending on qualifications.

Send curriculum vitae and names of three references to Dr James F Perdue, Lady Davis Institute for Medical Research — Sir Mortimer B Davis — Jewish General Hospital, 3755 Cote St Catherine Road, Montreal, Que Canada H3T 1E2. (NW760)A

LONDON SCHOOL OF **HYGIENE & TROPICAL MEDICINE**

(University of London) **EVALUATION AND PLANNING** CENTRE FOR HEALTH CARE ROSS INSTITUTE

A NURSE RESEARCH ASSISTANT

Required from 1st October 1981 to work in a multidisciplinary group concerned with health care in developing countries. Applicants should have had overseas as well as UK experience and preferably hold a degree or diploma in a relevant discipline. Salary in the range of £4,677 -£5,481 or £5,534 -£6,597 (under review) depending on experience and qualifications plus £527 London Weighting. The successful candidate will be required to travel overseas.

Application forms and further details from Dr J P Vaughan, EPC, 31 Bedford Square, London WC1. Telephone enquiries: 01-631 3216. (9124)A

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF **HAEMATOLOGY TECHNICIAN (GRADE 3)**

to assist a study of the sensitivity of leukaemic cells in culture to cytotoxic agents. Candidates must possess ONC in Medical Laboratory Science or appropriate equivalent as minimum qualification and experience in tissue culture techniques also an advantage. The post might be suitable for graduates.

This post is available for one year in the first instance.

Salary within range £4,672 -£5,474 per annum.

Application forms can be obtained from the Registrar, The University, PO Box 147, Liverpool L69 3BX. Quote Ref RV/855. (9173)A

UNIVERSITY OF OXFORD

DYSON PERRINS LABORATORY **POSTDOCTORAL** RESEARCH ASSISTANTSHIP

Applications are invited for a postdoctoral research assistantship (supported by SRC) to study stereo-

chemical effects on nuclear spin coupling between directly bonded carbon atoms.

Applicants should have experience in one or both of the following: (a) F T n m r and (b) synthesis with stable isotopes.

The appointment is for one year (from 1st October 1981, or up to 6 months later by agreement). The salary will be in the Research Support Grade 1A, the salary being not higher than £7,290 pa plus USS.

Applications (one copy), with curriculum vitae and names and addresses of at least two referees should be sent as soon as possible to Dr M J T Robinson, Dyson Perrins Laboratory, South Parks Road, Oxford OX13QY. (9088)A

MEDICAL RESEARCH COUNCIL **CLINICAL AND POPULATION CYTOGENETICS UNIT**

SCIENTIST GRADE II

Applications are invited for a SHORT-TERM NON-CLINICAL SCIENTIFIC post in this MRC Unit, tenable for 3 years. Candidates of immediately post-doctoral or equivalent status will be preferred.

The appointee will work with a group studying the biological effects of chemical mutagens and will be mainly involved with studies on induced DNA/chromosome damage in human cells. The post will be suitable for applicants interested in aspects of DNA repair and/or mutagenesis and interested candidates with some experience of cytogenetics are also invited to apply.

Remuneration will be at an appropriate point on the scales for university non-clinical academic staff. Further information may be obtained from Mr Alasdair Douglas, MRC Clinical and Population Cytogentics Unit, Western General Hospital, Crewe Road, Edinburgh EH4 2XU, Tel. 031-332 2471, with whom applications — including a full CV and the names and addresses of two professional referees - should be lodged (9178) Å by 18th September 1981.

Soil Scientist

£4,809 — £9,619 (under review)

Age Limit: Applicants must not be more than 55 years of age

on the closing date, i.e. born on or after 7th August 1926.

Closing date: 7th August 1981 Job Ref. SB76/81/NN. Tel. ext. 256

DEPARTMENT OF AGRICULTURE (NORTHERN IRELAND) AGRICULTURAL AND FOOD CHEMISTRY RESEARCH DIVISION

The succesful applicant will join a team engaged in research and advisory work in the various aspects of Soil Chemistry and Plant Nutrition and may also be required to undertake teaching duties in the faculty of Agriculture and Food Science, Queen's University, Belfast.

The main research objectives are to investigate factors controlling, and to study means of improving, the fertility of agricultural soils and the output of agricultural crops by related field, pot and laboratory studies.

Appointment will be at Senior Scientific Officer, Higher Scientific Officer or Scientific Officer level.

Senior Scientific Officer

Applicants must possess a First or Second Class Honours Degree in Soil Science, Chemistry, Agricultural Chemistry or related discipline with at least 4 years relevant post-graduate experience.

Higher Scientific Officer

Applicants must possesss an Honours Degree as above with at least 2 vears relevant post-graduate experience.

Scientific Officer

Applicant must possess an Honcurs Degree as above.

Preference may be given to candidates with appropriate post-graduate experience in Soils and/or Plant Nutrition.

The Civil Service Commissioners, by taking into account such factors as the applicant's educational qualifications, extent and duration of previous relevant experience, may decide to interview only those who appear to be best qualified.

Salary Scales (under review)

Senior Scientific Officer £7,644 — £9,619 Higher Scientific Officer £6,075 — £7,999 £4,809 - £6,480 Scientific Officer

In addition there is a non-contributory pension scheme apart from a 11/2 % deduction from salary to cover widows' benefit in the case of male officers

Grading and starting salary will be related to qualifications and experience.

These posts are open to both men and women. Please write or telephone for an application form (using the extension number indicated and quoting the job reference) to the Civil Service Commission, Rosepark House, Upper Newtownards Road, Belfast BT4 3NR (telephone Dundonald 4585). Completed forms must be returned to arrive not later than the closing date stated.

UNIVERSITY OF LEICESTER

DEPARTMENT OF GENETICS

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the above position, funded by the Medical Research Council, to investigate the mechanism of iron in plasmid-bearing bacteraemic strains of Escherichia coli, with particular emphasis on the organisation and function of specific membrane components. The post is available at any time after 1 October 1981; it is tenable for a period of 14 months and may therefore interest applicants returning from abroad.

The salary is on Range 1A for Research and Analogous Staff, plus superannuation.

Applications, with curriculum vitae and the names of two referees, should be addressed to Dr P H Williams, Department of Genetics, University of Leicester, Leicester LE17RH, from whom further details (9134)Aare available.

university college of

Research Demonstrators

Applications are invited for vacancies of Research **Demonstrator** in the Department of Zoology Applicants, who should be in possession of a PhD degree or have submitted for such a degree, should have specialised in mathematical ecology including computing, and biology of marine invertebrates and/or zooplankton.

The appointments, which will be for one year in the first instance, from October 1, 1981 will be on a scale up to £6,880 per annum.

Closing date for applications, Friday, 14th August, 1981.

Research Demonstrator

Applications are invited for the vacancy of Research **Demonstrator** in the Department of Geology. Applicants should either be in possession of a PhD or have such a degree near to completion.

The appointment, which will be for one year in the first instance renewable on an annual basis for maximum of three years, will be on a scale up to £6,880 per annum, together with USS/ USDPS benefits.

Closing date for applications, Friday, 7th August 1981.

Further particulars and applications forms (2 copies) for both posts may be obtained form the Personnel Office, University College of Swansea Singleton Park, Swansea SA2 8PP, to which office they should be returned by the above dates. (9161)A

UNIVERSITY OF READING **LECTURESHIP** IN ZOOLOGY

Applications are invited for a Lecturership in Zoology, tenable for a fixed term of one year from 1 October 1981. The duties will involve lecturing, tutorial and demonstrating work in applied zoology and expertise in entomology, agricultrual pests or genetics is essential.

Applications (two copies) from persons able to begin on 1 October, giving the names of two referees, should be sent to Professor K Simkiss, Department of Zoology, The University, Whiteknights, Reading RG6 2AJ, by 1 August. (9126)A

(probably on scale £4,672 £5,473) with interests in microbiology, biochemistry or

biology.
Further Details from Personnel Office, The University, Dundee DD1 4HN. Tel. 0382 23181 ext. 383. By August 13th 1981. (9143)A

UNIVERSITY OF SOUTHAMPTON **POST-DOCTORAL** RESEARCH FELLOW **Department of Biology**

Applications are invited from biologists with interests in Taxonomy to work with Dr F A Bisby and Dr R J White from 1 September 1981 to the end of July 1982 in the first instance. The SRC funded project involves building a data-base with morphological and chemical data on a tribe of the Leguminosae and experimenting with the provision of novel Taxonomic services for evaluation by a users' panel. The successful applicant will have an interest in the use of computer-based techniques in taxonomic problems.

Starting salary at the rate of £5,505 — £6,245 per annum + USS benefits.

Further particulars may be obtained from Mrs P C P Sears, Staffing Section, The University, Highfield, Southampton SO9 5NH to whom applications with curriculum vitae and names of two referees should be sent as soon as possible, and not later than 3 August 1981. Please quote reference number 1608/R.

-(9123)A.

CSIRO

AUSTRALIA

Principal Research Scientist/ Senior Principal **Research Scientist** (Research Fellow)

Division of Environmental Mechanics Canberra Act

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,400 employees - 2,500 of whom are research and professional scientists located in Divisions and Sections throughout Australia.

Field: Soil Physics.

General: Research in the Divisional deals with transport of energy, water salts and gases in the natural environment. The Division, located in Canberra, has 27 staff members, including 14 research scientists, working in areas of soil physics, solar radiation, fluid mechanics, micrometeorology and physical aspects of plant physiology

Duties: The soil physics program of the Division has concentrated on interaction between water and soil. The appointee will be expected to complement this program through theoretical work on porous medium physics and applied mechanics. The research will be directed in the first instance to studies of problems presented by systematic and random spatial variability of soils; to physical consequences of the interaction between soils and plants; and to the physics and physical chemistry of saline soils. The extension of theory to other areas of science and technology will be pursued.

The appointee will collaborate with other members of the program and with research officers of State instrumentalities.

Qualifications: A PhD or equivalent qualifications, and extensive experience and expertise in the areas of mathematical and physical research in soil water.

Salary: Principal Research Scientist/Senior Principal Research Scientist (Research Fellow) \$A29,638 - \$A38,921 pa.

Tenure: A fixed term appointment of three years is envisaged. Superannuation benefits available.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting reference number A4489 should reach: The Personnel Officer, Australian Scientific Liaison Office, Australia House, Strand, London WC2B 4LA by 24 August 1981. Applications in USA and Canada should be sent to: The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue NW, Washington DC 20036

Current vacancies in CSIRO appear on PRESTEL page 252903.

Royal Postgraduate Medical School

(University of London)

DEPARTMENT OF MEDICINE Senior Research Officer

Applications are invited from post-doctoral biochemists to join a Medical Research Council-supported research programme studying complement function in health and disease, particularly to characterise the molecular mechanisms of complement activation by antigen-antibody complexes and the effects of other complement activators in various diseases. Experience in immunochemistry is desirable.

Salary will be at an appropriate point on Range 1A, £6,070 -£10,575 plus £967 London Allowance.

Prospective applicants should write to Professor D. K. Peters enclosing a curriculum vitae and the names of two referees. Please quote reference 2/227. (9118)A

CSIRO AUSTRALIA

Research Scientist/ Senior Research Scientist (Research Fellow)

Division of Tropical Crops & Pastures **Northern Territory** Darwin

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,400 employees - 2,500 of whom are research and professional scientists located in Divisions and Sections throughout Australia.

Field: Crop Scientist (Soybean adaptation).

General: The Charles Darwin Laboratories are in the main scientific base for CSIRO research in north-western Australia. They accommodate 15 scientists from the Division of Tropical Crops and Pastures and Wildlife Research, have good library and statistical services, and a computer node linked to the CSIRONET system. The agricultural research programs are concentrating on rice, sorghum and soybeans and on animal production from dryland and irrigated pastures. Most of the field experiments are done at the Kimberley and Katherine Research Stations.

Duties: To undertake agronomic/ecophysiological studies on the adaptation of soybeans to agricultural environments in northern Australia. This will involve an extensive program of field experimentation under irrigated conditions during both wet and dry seasons and under dryland conditions.

Salary: Research Scientist/Senior Research Scientist (Research Fellow) \$A19,662 - \$A28,564 pa

Tenure: The position is available for a three year term with a possible extension for a further two years. Superannuation benefits available

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting reference number A5905 should reach: The Personnel Officer, Australian Scientific Liaison Office, Australia House, Strand, London WC2B 4LA by 24 August 1981. Applications in USA and Canada should be sent to: The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue NW, Washington DC 20036.

Current vacancies in CSIRO appear on PRESTEL page 252903.

The Royal Marsden Hospital, Downs Road, Sutton, Surrey

Medical Physics Technician GRADE III

Salary scale £5,750 - £7,277 p.a. (increase pending)

We are looking for a technician to complete a team of three in an in vitro laboratory carrying out mainly routine tests involving radioisotopes. The work is rewarding and requires an interest in patient contact.

Applicants should hold either an appropriate science degree, ONC, HNC, HND or equivalent qualification and have had at least 3 years similar technical experience.

For an application form and job description please contact the Personnel Department Royal Marsden Hospital, Fulham Road, London SW3 - Tel: 01-352 8171 ext 446.

Closing date: 14th August 1981.

(9174)A

INSTITUT PASTEUR PARIS-FRANCE

Applications are invited for a position of staff and POSTDOCTORAL RESEARCH SCIENTIST

with experience in molecular genetics, recombinant DNA techniques, and animal cell culture.

The genetic engineering laboratory involved in medical and industrial applications, is located on the Institut Pasteur Campus and has contact with fundamental research units.

Knowledge of French is not essential.

Applications with curriculum vitae and requested salary should be sent to: Monsieur le Directeur du Personnel, Institut Pasteur Paris, 28 Rue Du Docteur Roux, 75724 Paris, Cedex 15, France (W385)A

PRINCETON UNIVERSITY THE DEPARTMENT OF

BIOMEDICAL SCIENCES ASSISTANT PROFESSOR **OF BIOCHEMISTRY**

invites applications for tenure-track positions at the Assistant Professor level. Candidates should have a strong background in molecular biology, molecular genetics or bio-chemsitry and demonstrated excellence in research. An interest in eukaryotic organisms is preferred.

Applicants should submit a complete curriculum vitae, including a list of references and a description of their future research program to Dr S J Flint, Biochemical Sciences, Princeton University, Princeton NJ

Princeton University is an affirmative action/equal opportunity employer. (NW769)A employer.

UNIVERSITY OF DURHAM

DEPARTMENT OF GEOLOGICAL SCIENCES

Applications are invited for the post of

POSTDOCTORAL SENIOR RESEARCH ASSISTANT

tenable for three years from 1 August 1981, to work on the processing of seismic reflection data. The work will involve running the existing pro-cessing laboratory based on PDP-11 mini computer, documenting and expanding the existing software library, writing some systems software and processing seismic reflection data obtained on cruises off E. Greenland and the Lesser Antilles.

Applicants need not necessarily have a PhD, but equivalent experience and a strong computing background are essential. Salary is on the Research Scale 1A according to age, starting at £6,070 per annum at age 24, plus USS.

Applications (3 copies) naming three referees should be sent as soon as possible to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE. (9160)A

UNIVERSITY OF OTAGO Dunedin, New Zealand

LECTURER IN **PHYSIOLOGY**

Applications are invited from graduates with a research interest in membrane cellular and epithelial physiology for appointment as Lecturer in Physiology.

Salary within the scale: NZ\$19,140 - NZ\$23,520 per annum, according to qualifications and experience.

Further information may be obtained from Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H0PF or from the Registrar of the University. Additional detailed information may be obtained from Professor D W Taylor, Department of Physiology, University of Otago Medical School, PO Box 913, Dunedin, New Zealand.

Applications close on 31 August (9141)Ă

UNIVERSITY OF CANTERBURY Christchurch, New Zealand

LECTURER IN ASTRONOMY OR PHYSICS

Applications are invited for the above-mentioned position. The appointee must be prepared to take an active part in one of the experimental research fields of the Department; namely Astronomy, Solid State Physics or Atmospheric Physics.

Applications close on 31 October 198Î

The Salary for Lecturers is on a scale from NZ\$19,140 to \$23,520 per annum.

Further particulars and Conditions trom the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H0PF.

UNIVERSITY OF **EXETER**

DEPARTMENT OF PHYSICS POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited from suitably qualified candidates to take part in a research programme to investigate methods of studying air layers surrounding grinding wheels rotating at high speeds. The research programme, which is funded by SERC, is initially for one year. Some experimental experience in fluid flow measurement together with a strong theoretical interest in high speed fluid flow would be desirable. within the range £6,070 - £6,880 pa, placement depending on age and experience.

Applications including a curriculum vitae and names of two referees should be sent to the Personnel Office (Appointments), University of Exeter, Exeter, Devon by 25th August 1981. Please quote reference (9119)A No.7176.

Plant Biologist

The Plant Genetics Department of Pfizer Central Research is looking for creative individuals to participate in a multi-disciplinary research program for crop improvement. This department provides basic research support for the corn and soybean breeding programs of Pfizer Genetics, Inc.

Applicants should have strong formal training in plant biology, agronomy or crop science at the MS level. Experience in one or more of the following areas is desirable; plant tissue culture; genetics; stress physiology; field crop breeding methods; plant pathology.

In addition to an exceptional opportunity for professional recognition and growth, we offer a comprehensive salary/benefits package and attractive Connecticut shore living. Please send résumé and brief description of research interests to:

Ms. Lorraine C. Corr, Pfizer Central Research, Eastern Point Road, Groton, CT 06340.

An equal opportunity employer

(NW767)A

POST-DOCTORAL POSITION

Available immediately for studying changes in immune regulation in aged mice.

Send curriculum vitae and three letters to: Dr R M Gorcynski, Ontario Cancer Institute, Canada. c/o Nature Box xxx, 15 East 26th Street, Suite 1503, New York, NY 10010 (NW772)A

UNIVERSITY OF LEICESTER DEPARTMENT OF

DEPARTMENT OF CHEMISTRY

POSTDOCTORAL RESEARCH ASSOCIATESHIP IN ORGANIC CHEMISTRY

Applications are invited for a postdoctoral research associateship supported by the SRC, to work in collaboration with Dr P R Jenkins on the development of a synthetic approach towards the taxane group of natural products. Applicants should have interest and experience in synthetic organic chemistry.

The appointment, in Research Support Grade 1A, is initially for one year (from 1 October 1981) and is renewable for a second year. The starting salary is in the range £6,070 — £6,475 plus USS benefits.

Applications with curriculum vitae and the names and addresses of two academic referees should be sent as soon as possible to Dr P R Jenkins, Department of Chemistry, The University, Leicester LE1 7RH.

(9135)A

UNIVERSITY COLLEGE LONDON

RESEARCH ASSISTANT

NEUROPHARMACOLOGY

to study the release of neurotransmitters during the development of experimental epileptogenic activity. Applicants should have finished or be finishing their PhD programme. Salary from £5,675 pa + London Allowance + USS for 3 years.

Curriculum vitae to Dr R A Webster, Department of Pharmacology, University College London, Gower Street, London WC1E 6BT.

STANFORD UNIVERSITY California

Applications are invited for an opening at the

ASSISTANT PROFESSOR

level in the newly-formed Program in the History of Science.

Candidates should have demonstrated ability in the area of 19th and 20th century physical science.

Curriculum vitae and the names of at least two referees should be sent before November 15, 1981 to: Professor Eric Hutchinson, Academic Secretary, Stanford University, CA 94305.

Stanford University is an equal opportunity employer. (NW762)A

Director of Technical Liaison

Cetus Corporation, a leader in the commercial application of biotechnology, is seeking a microbiologist/geneticist with practical experience over a broad base of biological applications to coordinate the scientific aspects of the Company's proprietary base. The successful applicant will be the liaison between inventors and the patent counsel, continually maintaining an overview of corporate science with the aim of identifying and developing new concepts and discoveries as they emerge, as well as playing a significant role in corporate scientific strategy. The scientific aspects of corporate licensing will also be a responsibility.

This important staff position will be attractive to mature scientists who wish to move from the laboratory to an administrative role without losing detailed, hands-on involvement in this rapidly developing field.

The successful applicant will join an outstanding team of scientists and managers in a highly motivated, goal-oriented atmosphere. Please send C.V. and salary expectations, in confidence, to Cetus Corporation, Box "NG", 600 Bancroft Way, Berkeley, California 94710. An equal opportunity employer.

(NW758)A

cetus

YOU HAVE GOT A BRIGHT IDEA

TO FIND OUT BIOLOGICAL OR CHEMICAL COMPOUNDS

WE HAVE THE CAPITAL TO DEVELOP THESE NEW DRUGS

We are not a pharmaceutical firm, but a swiss based independant financial group, and we are prepared to let you participate in a capital venture for the exploitation of your project.

Our object: the development of new biological or chemical products (which have previously had a pharmacological screening) up to the stage of clinical tolerance and effectiveness required to permit licensing negotiations.

To obtain all the information required for initial selection, please write in English, French or German to: DEBIOPHARM S.A. Petit-Chêne 38 - 1001 LAUSANNE (Switzerland).

(W368)A

Experimental Officer

This is an excellent opportunity to join a team dedicated to the discovery and practical application of synthetic and natural regulators of the immune system. The successful candidate will have ample opportunity to contribute to the development of this recently established project and to collaborate with scientists in other disciplines.

You should have a biological degree or equivalent qualification and a knowledge of immunological techniques and theory. Experience of tissue culture and radio-immunoassay techniques would be an added advantage.

Conditions of service, salary and relocation assistance are designed to attract and retain staff of a high calibre. Our modern research laboratories are situated in pleasant surroundings but within easy reach of main road and rail routes.

Please send full C.V. to:

Mr. R. Yates, Personnel Officer, Imperial Chemical Industries P.L.C., Pharmaceuticals Division, Mereside, Alderley Park, Macclesfield, Cheshire.

Closing date for applications: August 31st 1981.

(9179)A

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF BIOCHEMISTRY Applications are invited for the post of DEMONSTRATOR/SENIOR

DEMONSTRATOR

in the Department of Biochemistry. The duties of the post will start on 1st October, 1981.

Salary within the range £5,285 — £7,700 per annum.

Applications, together with the names of three referees, should be received not later than 7th August, 1981, by The Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref. RV/854. (9144)A

THE INTERNATIONAL CENTER FOR AGRICULTURAL RESEARCH IN THE DRY AREAS (ICARDA)

has a vacancy for the post of LIBRARIAN

at its Research Station in Aleppo, Syria. Starting date: January 1, 1982. Qualifications and experience required: MSc or PhD degree in Library Science; fluent English and Arabic; working knowledge of agriculture; working experience in the Arab World.

Applicants should send their c.v. and write for further details to: The Personnel Officer, ICARDA, PO Box 5466, Aleppo, Syria. (W384)A

PROFESSORSHIP in the Clinical Smell and Taste Research Center at the University of Pennsylvania. Established scientist working in olfactory neurophysiology in Physiology and/or Otorhinolaryngology Department. Based in VA Hospital. Preferably with an MD degree. Write to Dr James B Snow, Jr, Department of Otorhinolaryngology and Human Communication, 5th Floor Silverstein, Hospital of the University of Pennsylvania, Philadelphia, Pennsylvania 19104 and provide three letters of reference. The University of Pennsylvania is an Equal Opportunity/ Affirmative Action Employer.

(NW751)A

STUDENTSHIPS

THE HANNAH RESEARCH INSTITUTE (University of Glasgow) POST-GRADUATE STUDENTSHIP

Applications are invited for a PhD studentship tenable at the Biochemistry Department to study aspects of the regulation of lipid metabolism in the mammary gland.

Applicants must possess or expect to obtain a First or Upper Second Degree in Biochemistry and should write (including c.v. and names of two academic referees) to: The Secretary, The Hannah Research Institute, Ayr KA6 5HL, Scotland. (9130)F

UNIVERSITY OF ABERDEEN

DEPARTMENT OF BOTANY
SRC CASE
STUDENTSHIP

Applications are invited from candidates with a first or upper second class honours degree in Botany or Microbiology for a three year CASE studentship on the Biology of Soft Rot Erwinias on Potato Leaves.

The research will be carried out at the University of Aberdeen (under the supervision of Dr J P Blakeman) and at the Scottish Crop Research Institute, Dundee (under the supervision of Dr M C M Pérombelon).

Applications, including curriculum vitae and names of two referees should be sent as soon as possible to Dr J P Blakeman, Department of Botany, University of Aberdeen, St Machar Drive, Old Aberdeen AB9 2UD. (0224) 40241) from whom further information may be obtained. (9133)F

THE CITY UNIVERSITY

DEPARTMENT OF OPTOMETRY AND VISUAL SCIENCE

TWO RESEARCH STUDENTSHIPS IN VISUAL SCIENCE

Applications are invited from graduates with a good honours degree for research towards a PhD on either: "Flicker and Movement Detection as a Function of Field Scan Direction in Television Systems," or "Photometry and Visual Performance Under Conditions of Chromatic Adaptation". The projects are suitable for graduates in Physics, Optics, Ophthalmic Optics, Physiology, Electronic Engineering or related communications subject.

Further details and application forms can be obtained from: Dr J E Saunders, Department of Optometry and Visual Science, The City University, Dame Alice Owen Building, 311-321 Goswell Road, London EC1V7DD. (9139)F

UNIVERSITY OF CAMBRIDGE Scott Polar Research Institute

NERC RESEARCH STUDENTSHIP

Applications are invited from mathematicians, mathematical physicists or oceanographers for a PhD studentship in one of the following

1) The physical oceanography of the marginal ice zone.

2) Sea ice rheology from submarine sonar profiles.

Applicants who have or expect to obtain a 1st or upper 2nd degree should contact Doctor V A Squire at Scott Polar Research Institute, Lensfield Road, Cambridge CB2 IER (tel 0223-66499 ext 411) as soon as possible. (9167)F

UNIVERSITY OF KENT AT CANTERBURY BIOLOGICAL LABORATORY

SERC CASE STUDENTSHIP

Applications are invited for an SERC CASE studentship leading to the degree of PhD and tenable from 1 October 1981 for research on lignin degradation and subsequent aromatic metabolism by cultures of the edible mushroom Agaricus bisporus. The project will be supervised by Dr R B Cain in collaboration with Dr D A Wood of the Glasshouse Crops Research Institute.

Applicants should have a first or second class honours degree in Biochemistry, Microbiology or Botany.

Applications, giving details of qualifications and the names of two academic referees should be sent to the Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH from whom further details may be obtained. Closing date 7 August 1981. Please quote ref. PG14/81/N. (9140)F

(9159)M

ASSISTANTSHIPS

THE UNIVERSITY OF SHEFFIELD DEPARTMENT OF CERAMICS, GLASSES AND POLYMERS

RESEARCH ASSISTANTSHIP

Applications are invited from men and women for the above post, to develop the technique of cryogenic scanning electron microscopy and apply it in the investigation of structure in dispersions of clays, oxides and other ceramic materials. The results obtained will be used to interpret the rheological, sedimentation and filtration characteristics of such systems. This project supervised by Dr B Rand is financed by SRC. Tenable for 3 years.

Initial salary up to £6,880 depending on age and experience. An honours degree in a physical science subject and research experience (preferably to PhD level) required. Experience colloid science or scanning electron microscopy desirable, though not essential.

Applications, including the names and addresses of two referees, should be sent to the Registrar and Secretary, the University, Sheffield \$10 2TN by 7 August 1981. Quote ref: R615/G (9171)P

UNIVERSITY OF OXFORD

Dyson Perrins Laboratory

POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for a post-doctoral research assistant, supported by MRC, to study the mechanism of action of polyene macrolides by nuclear magnetic resonance. Candidates should have experience of chemical or biological applications of high field NMR and/or an interest in biological organic chemistry.

Letters of application should reach Dr J M Brown, Dyson Perrins Laboratory, South Parks Road, Oxford OXI 3QY as soon as possible, and contain a full curriculum vitae and the names of two referees. Salary will be on Research Support Grade 1A up to £6,882 pa plus USS according to age and experience, and appointment for one year in the first instance, from 1st October 1981 or a mutually convenient alternative date. (9150)P

UNIVERSITY OF SOUTH FLORIDA MEDICAL CENTER POSTDOCTORAL RESEARCH ASSISTANTSHIP IN BIOCHEMICAL TOXICOLOGY

Position is available immediately for aggressive individual with doctorate in pharmacology-toxicology. Program involves pulmonary metabolism and response to certain drugs and industrial chemicals. Strong background in biochemistry and physiology a must.

Send CV and 3 letters of recommendation to: Mark R Montgomery, PhD, Research Service (151), VA Hospital, 13000 N 30th Street, Tampa, Fl 33612.

(NW768)P

GRANTS and SCHOLARSHIPS

THE UNIVERSITY OF SYDNEY

RICHARD CLAUDE MANKIN SCHOLARSHIP

Applications are invited for the above-mentioned scholarship from graduates wishing to undertake research related to water conservation.

The award is at postdoctoral level (\$A17,083 — \$A19,075 per annum). Travel grants for overseas Fellows may be payable. An award may also be made at postgraduate level (\$A4,620 per annum plus allowances where appropriate).

Further information and application forms are available from the Registrar (Scholarships Section), University of Sydney, NSW 2006, Australia, with whom applications close on 31 October 1981.

(9148)H

THE UNIVERSITY OF SYDNEY FACULTY OF AGRICULTURE

Applications are invited from graduates for

AGRICULTURAL SCHOLARSHIPS

offered by the University of Sydney and tenable in the Faculty of Agriculture for 1982.

The object of the Scholarship is to encourage and promote scientific study within the Faculty of Agriculture.

Research is undertaken in the following agricultural disciplines: Agronomy, Animal Husbandry, Biometry, Chemistry, Economics, Entomology, Extension, Genetic and Plant Breeding, Horticulture, Microbiology, Plant Pathology, Soil Science.

The Scholarships will provide a stipend of \$A4,620 plus other allowances.

Further information and application forms are available from the Registrar, Scholarships Section, University of Sydney, NSW 2006, Australia, with whom applications close on 31 October 1981.

(9147)H

CONFERENCES and COURSES

International Genetic Sciences, Inc. is organizing an annual conference on Introduction of Genetic Materials into Eucaryotic Cells: Present State and Future Prospects

Among the Lecturers:

H. Goodman (U. of Calif, S.F.), A. Graesman (Free University of W. Berlin), S. Itzhar (Volcani Center, Israel), A. Loyter (Hebrew U. of Jerusalem), D. Papahadjopoulos (U. of Calif, S.F.), F. Ruddle (Yale U.), W. Rutter (U. of Calif, S.F.), R. Rott (inst. of Virology, Gissen, W. Germany), R. Shimke (Stanford U.)

Among the topics to be included:

- 1. Transfer of Nucleic Acid into animal cells.
- 2. Introduction of genes into plant cells.
- 3. Use of Liposomes as a carrier of biological materials.
- Fusion mediated transfer of biological materials into animal cells.

Cost of \$450 includes room and meals. No registration fees. Number of participants limited to sixty. The conference to be held at the Harrison Conference Center, Glen Cove, L.I., N.Y. Arrival Nov.22, 1981; departure Nov.25, 1981.

Interested scientists, please send as soon as possible information including name, address, phone, present position and areas of interest. Send to:

International Genetic Sciences, Inc. 155-25 Styler Rd, Jamaica, NY, USA 11433 or call (212) 526 0400 (NW761)C

UNIVERSITY OF SUSSEX

MSc IN BIOCHEMISTRY

This full-time, one year course can provide a training in general Biochemistry. Alternatively, applicants may specialize in either Biochemical Endocrinology or Plant Biochemistry and Bioenergetics. Research projects comprise a major part of the course, and are related to research currently underway in the Biochemistry Group, much of which is of immediate relevance to developing countries.

Applicants should normally possess a degree, or its equivalent, in Biochemistry or in a Biological, Chemical or Medical Science. Enquiries for further information and applications for the 1981/82 or 1982/83 sessions should be sent to the Subject Chairman of Biochemistry, School of Biological Sciences, University of Sussex, Falmer, Brighton, Sussex BN1 9QG.

UNIVERSITY OF KENT AT CANTERBURY Faculty of Social Sciences STUDIES IN DISABILITY

Applications are invited for two courses which will begin in January 1982: (i) Diploma in Social Work and Physical Handicap (recognised by CCETSW) (ii) Certificate in Disability Studies.

The Diploma Course is full-time and lasts for nine months and is intended for Social Workers and other professionals in the Health and Social Services.

The Certificate Course is parttime, with teaching confined to four mornings a week for one University term. In addition a dissertation has to be completed within nine months of registration. This course is for anyone who has an interest in or wishes to update their knowledge of disability, including professionals who are unable to attend the full-time course.

Teaching facilities on the Diploma and Certificate Course will be shared.

For informal discussions about either course, contact Dr Mike Oliver at University of Kent. Tel: 0227 66822, ext 7491.

For applications and further details write as soon as possible quoting Ref PG15/81/HSS to: Senior Assistant Registrar, Faculty of Social Sciences, The Registry, The University, Canterbury CT2 7NZ

(9155)(

Travelling Fellowships 1982-83

Applications are invited for Travelling Fellowships to be taken up in 1982-83. The scheme enables clinical and non-clinical biomedical research workers to undertake advanced specialised training overseas, or more senior workers (including academic or research staff on paid leave from permanent appointments) to collaborate with colleagues abroad, for periods of three months to two years (normal tenure one year).

Candidates must have been ordinarily resident in the UK, the Channel Islands or the Isle of Man throughout the three years preceding the application date. Medically or dentally qualified candidates should be of at least NHS Registrar (or equivalent) status with some research experience. Non-clinical candidates should hold a PhD/DPhil.

Further information and application forms may be obtained from: Training Awards Group, Medical Research Council, 20 Park Cescent, London W1N 4AL, (Telephone: 01-636 5422 Ext. 448).

The closing date for receipt of applications is 30 September 1981.

(9142)E

MONASH UNIVERSITY Melbourne, Australia DEPARTMENT OF MATERIALS ENGINEERING RESEARCH FELLOWSHIP IN CORROSION ENGINEERING

As part of an enquiry into the feasibility of setting up an Australian National Centre for Corrosion Prevention and Control a Research Fellow is required to help assess both the actual need for, and the likely benefits to accrue from the establishment of such a Centre.

The appointee will probably already have some postdoctoral experience, but applicants with lower academic qualifications and a wide range of experience are encouraged to apply.

Appointment initially for 1 year within range \$A17,083-23,373. Enquiries to Dr B W Cherry, in the University.

Applications including Ref no 25362, curriculum vitae and 2 referees to the Registrar, Monash University, Clayton, Victoria 3168, Australia, with copy to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF by 15/8/81. (9115)E

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF PHYSICS

RESEARCH FELLOWSHIP

Applications invited for this SERC-funded post in Nuclear Structure Physics, tenable from 1st October 1981 until 31st January 1984. Successful candidate expected to participate in charged particle spectroscopy studies using polarized ³He beams from the Department's Radial Ridge cyclotron and heavy ions from NSF tandem accelerator nearing completion at Daresbury Laboratory. Daresbury experimental facilities include large scattering chamber and Scanditronix QMG2 magnetic spectrometer.

Salary on Research Fellow 1A scale £6,070 to £10,575 plus superannuation. Maximum starting salary £6,880.

Further particulars from Assistant Registrar (Sc and Eng), PO Box 363, Birmingham B15 2TT, to whom applications (three copies) including full curriculum vitae and naming three referees should be sent not later than 15th September 1981.

Please quote ref: ND2. (9156)E

MASSEY UNIVERSITY Palmerston North, New Zealand

POST-DOCTORAL FELLOWSHIPS

Applications are invited for Post-doctoral Fellowships tenable in any Department of the University.

The academic activities of the University are grouped under the following faculties and schools. Opportunities for study and research are available in the following fields:

AGRICULTURAL AND HORTICULTURAL SCIENCE — Agricultural Economics and Marketing; Farm Management; Agricultural Engineering; Agronomy; Animal Science (Dairy, Sheep, Beef, Pigs); Horticultural Science and Plant Health; Poultry Science; Soil Science.

BUSINESS ADMINISTRATION — Agricultural Business; Business Studies and Business Law; Data Processing; Economics; Financial Management and Accounting; Personnel Administration.

FOOD SCIENCE AND BIOTECHNOLOGY — Food Technology; Biotechnology (i.e. processing of Biological Materials); Industrial Management and Engineering; Industrial Management and Industrial Mathematics.

HUMANITIES - English; History; French; German; Philosophy.

SCIENCE — Biochemistry; Biophysics; Botany; Chemistry; Genetics; Microbiology; Zoology.

SOCIAL SCIENCE — Computer Science; Economics; Education; Geography; Mathematics; Psychology; Regional Planning; Social Anthropology; Sociology; Social Work; Statistics.

VETERINARY SCIENCE — Physiology and Antomy; Veterinary Pathology and Public Health; Clinical Sciences.

Information concerning the research activities of the departments associated with these groups are given in the University Calendar. Intending applicants are advised to write to the Head of the appropriate department in the course of preparing an application.

The Fellowship will be tenable for one year, with possible extensions, and carries an emolument of NZ\$15,755 per annum inclusive of an allowance of up to NZ\$2,205 toward return fares.

Further details of the position and the University, together with conditions of appointment and information to be supplied by applicants, may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close on 15 August 1981.

(9125)E

UNIVERSITY OF ABERDEEN

DEPARTMENT OF MICROBIOLOGY POSTDOCTORAL

RESEARCH FELLOWSHIP

Applications are invited for a postdoctoral Research Fellowship to join a group led by Professor W A Hamilton working on the fouling and corrosion of steel structures in the North Sea. This is a joint project with the School of Mechanical and Offshore Engineering at Robert Gordon's Institute of Technology and is financed by the SERC Marine Technology Directorate.

Appointment will be from 1st October 1981 and will be for one year in the first instance.

Salary within Range 1A £6,070 — £10,575 per annum, with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by Friday 7 August 1981. (9083)E

UNIVERSITY OF KENT AT CANTERBURY BIOLOGICAL LABORATORY POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited for an SERC-supported post of Postdoctoral Fellow to work with Dr C J Knowles on the formation of haemoproteins in Streptococcus species. A PhD in either biochemistry or microbiology will be required. Experience of protein purification or immunology would be helpful but is not essential. The post is available for up to 3 years from October 1981. The initial salary will be in the range of £6,070 to £6,880 pa.

Applications with a curriculum vitae and the names of two referees should be sent, as soon as possible, and not later than 21 August 1981, to Mr JS Cowie, Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH from whom further particulars may be obtained. ARE YOU STILL READING SOMEONE ELSE'S COPY OF ISIS?

IF SO, now is the time to enter your own subscription. **Isis**, the official journal of the History of Science Society, is the leading journal in the field.

Isis keeps over 3300 subscribers in nearly fifty countries up to date on all developments in the history of science with articles, critiques, documents and translations. Along with these, its notes and correspondence and news of the profession provide useful information to professionals, educators, scholars and graduate students.

Lively essay reviews and over 200 book reviews a year cover every specialty in the history of science, technology and medicine.

In addition to your four quarterly issues of Isis you will also receive:

- Membership in the History of Science Society.
- —The annual *Critical Bibliography* listing over 3500 publications in the history of science, technology and medicine from the preceding year.
- —The *Triennial Guide* containing directories of members and scholarly programs and information on 90 journals in the field.
- —The quarterly *Newsletter* providing current news of the profession, including employment opportunities and approaching meetings.

Toxicology is the study of the reactions, both adverse and compensatory, of living creatures to noxious materials. The hazards to which man is exposed and the manner in which he reacts to them from the moment of conception and thereafter throughout life is the subject of Human Toxicology. This new journal embraces both animal research, where it has a direct significance for man, and studies on man himself. These studies may be biochemical, physiological, pathological, clinical and epidemiological but will all be designed to increase our understanding of the action of noxious substances in the body and of means to counter their effects. All papers will be subject to peer review.

Main Features

The following material will appear on a regular basis:

* Original papers of a high scientific standard on all aspects of human toxicology, embracing both animal research and studies with humans

1:87

PUBLISHERS

- * Short communications
- * Invited comment on current matters of professional interest
- * Editorials on topical issues
- * Review papers
- * Book reviews

Call for Papers

The submission of suitable papers for editorial consideration is welcomed. Papers must be in English and two copies should be submitted. References, collected at the end of the paper, should include the author's name, year of publication, title of article, title of publication, volume number and first and last page numbers. They should be listed in alphabetical order. A detailed list of *Instructions to Authors* can be obtained from the Publisher. Papers should be sent directly to the Editorial Secretary, Human Toxicology, 4 Little Essex Street, London WC2R 3LF England, or to Human Toxicology, Nature, Suite 1503, 15 East 26th Street, New York, NY 10010, USA.

INTRODUCING

BRL Chromatography Columns

- Versatile, Top Quality Columns at Reasonable Pricesfor ion exchange, gel filtration, affinity and adsorbent chromatography.
- Wide Range of Column Sizes—from 0.9 x 15 cm (9.4 ml bed volume) to 15 x 100 cm (17,700 ml bed volume).
- Borosilicate Glass and Polypropylene Construction for aqueous systems. Teflon end plates and adjustable plungers are available for organic solvent systems.
- Adjustable Plungers—can be added to reduce extra-bed mixing or for ascending flow systems. Can be installed from either or both ends of the column.
- Moderate Pressures—(20-125 p.s.i. depending upon column size) can be used to increase or stabilize flow rates.
- Columns Dismantle Completely—for easy cleanup.
- Side Vent Port—on top end plate for bleeding air or sample addition.
- End Plates Adapt to Commercial Tubing—no special tubing or flaring tool required.
- Unique Non-Clogging Bed Support—consisting of a thin 10μ membrane suspended over a woven grid minimizes dead volume.

And Accessories

- Packing Reservoirs
 Water Jackets
- Column Extenders
 ◆ Adjustable Plungers
 ◆ Valves and Tubing

How Britain runs its Science

This highly successful wallchart, which first appeared in 1975, has now been completely revised and updated.

The 2×3 ft guide offers a comprehensive survey of the administration of British science. It provides a full account of the funding of science in Britain, giving details of money spent by government, research councils, industry and universities.

Designed as a fold-out sheet, it can be carried easily to meetings or hung as a wall poster for permanent reference. The new 1981 edition is available at £3.50 or \$7.95 by sending your cheque to either Nature's London or New York offices.

In the UK and elsewhere: Nature, 4 Little Essex Street, London WC2R 3LF, England.

In the US and Canada: Nature, Suite 1503, 15 East 26th Street, New York, NY 10010, USA.

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). A draft abstract (50 words) is required.

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature

Manuscripts may be submitted either to London or New York (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the World List of Scientific Periodicals, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

X-RAY **MICROANALYSIS** IN BIOLOG

Edited by M.A. HAYAT

Professor of Biology at Kean College of New Jersey

June 1981; £30.00; 500pp; ISBN 0 333 32355 6

CONTENTS

Principles and Instrumentation -A.T. Marshall; Preparation of Specimens: Changes in Chemical Integrity — A.J. Morgan; Frozen-Hydrated Specimens — A.T. Marshall; Frozen-Hydrated Sections - A.T. Marshall; Sections of Freeze-Substituted Specimens - A.T. Marshall; Influence of Specimen Topography on Microanalysis — F.D. Hess; The Skeletal Muscle — M. Sjostrom; Liquid Droplets and Isolated Cells -J.V. Bonventre, K. Blouch and C. Lechene; Quantitative X-Ray Microanalysis of Bulk Specimens - F.D. Ingram and M.J. Ingram; Quantitative X-Ray Microanalysis of Thin Sections - G.M. Roomans; Index.

This is the first book dealing exclusively with x-ray microanalysis of biological specimens. It not only presents the basic theory and operation of the instruments used for producing, measuring and interpreting x-ray signals, but also describes in detail the preparation of bulk specimens, sectioned specimens and fluid specimens.

The book includes both qualitative and quantitative analysis of biological materials and it discusses application of x-ray microanalysis to pathology, physiology and cytochemistry.

Instrumentation is presented in a concise manner and methodology in detail. Almost all instruments are covered, including TEM, SEM and STEM. Instructions are given on how to produce, measure and interpret x-ray signals and emphasis is given to the aspects of instrumentation that are of practical use. In its comprehensive compilation of methods for preparing biological specimens the advantages and disadvantages of alternate methods are discussed.

READERSHIP: Electron Microscopy, Biology, Biochemistry.

LEVEL: Undergraduate and graduate students, researchers and research technicians.

Cladistics and evolution on display

How should museums of natural history exhibit specimens? Is cladistics a proper framework? And is it too agnostic—soft on Neo-Darwinism? The last contribution to the correspondence on these topics is on page 403.

The role of the technique of classification called cladistics in the museum's exhibition policy evidently appears to many at the museum to be one of the chief issues to have been raised. The letter from Dr Roger Miles, the director of the Public Services Department at the museum (which plans and mounts exhibitions), and his colleague Dr G.C.S. Clarke on page 402 defends the decision, in two of the recent exhibitions, that the relationship between specimens displayed should be described in cladistic terms - what first set Halstead off. The decision is justified on "educational grounds", presumably the argument that visitors to these exhibitions should be provided both with an understanding of how phylogenetic relationships may be inferred by objective means (which is one of the undoubted virtues of cladistics, at least when meaningful correlations are obtainable) and with a sense of the uncertainty running through phylogeny. This is consistent with the principles on which curriculum development in high-school science have been constructed in the past twenty years. But museums are not high-school classrooms, in which good teachers can ensure that students appreciate the basis on which their work is carried out. Most visitors to museums see what is displayed but once. To fail to record, for such people, that in the opinion of most palaeoanthropologists, Homo erectus is the most likely precursor of Homo sapiens, is to lose an important opportunity - and to avoid answering questions in many visitors' minds about the importance of recent discoveries in East Africa. And to fail to make explicit the principles on which these exhibitions were designed is to ask for trouble from people such as Halstead, caught up as they are with the argument about the validity of cladistics as a way of classification and as a cloak

Technically, cladistics has respectable origins, not least in the development of numerical taxonomy twenty years ago. Inevitably, however, the precision of a cladistic classification of fossil material is limited by the amount and variety of material available for analysis. Out-and-out cladists may hold that phylogenetic relationships not demonstrated by their techniques have no place in the interpretation of the fossil record and much of what they say makes philosophical sense. On present information, for example, there is no way of telling whether Archaeopteryx is the ancestor of all birds or (more probably) an early version of a bird. But pedantry can be carried too far, especially in public exhibitions. Although there may be cladistic doubt (represented by some such statement as "P < 0.1") about the relationship

between *Homo erectus* and *Homo sapiens*, do not the methods of classical palaeoanthropology, with all the appropriate qualifications, deserve a place in public exhibitions because they are stimulating, provoking?

A more serious difficulty, in the course the museum has elected to follow, is that the technique is best at sporting branching points in familial relationships, and says little about gradual transformations within a single population so profound that they are tantamount to a qualitative transformation. No wonder that Halstead fears that cladism is a refuge for those who believe in punctuated equilibrium. But, while he may be able to marshal substantial evidence for the moderate assertion that many Marxist evolutionists are cladists, the proposition that all cladists are Marxists — which has not seriously been suggested by anybody, but only inferred — has no place in logic. It would in any case, as Sir Andrew Huxley said in his attack on *Nature* on 27 May, be intolerable that such a reading of events should be held to be part of the case against cladistics.

The other serious objection to the modelling of public exhibitions within the framework of cladistics is that the framework is inherently agnostic. When the numerical correlations are too small to be significant when assessed against arbitrary criteria, relationships cannot be asserted. Although, even in exhibitions mounted for the general public, statements such as that "the case for thinking that Homo erectus was the precursor of Homo sapiens is not proved" may have a place, part of the trouble at the museum (to which there has been no reply) is that agnosticism has gone too far. Did evolution happen? The museum has cladistically not committed itself. Is Darwinism a "proper" scientific theory, in some sense of that word? The museum has withdrawn the obscure film that suggested to anybody who paused in passing that it is all a gigantic muddle; people will be looking, in the months ahead, at the museum's strategy for retreating from this gaffe. The difficulty, with which everybody must sympathize, is that all museums of natural history are used not merely by those who wish to answer questions in their minds about evolution and the like but also by those who believe that Darwinism is an abomination.

Several other issues remain to be resolved. The aesthetics of the museum's plans for the future have been questioned, and rightly. Is the new building really necessary? Is the push-button public exhibition the only acceptable modern style? Most certainly not. Was Sir Andrew Huxley's attack on Nature (for publishing alleged irrelevancies) just? Readers must judge for themselves. It is understandable that a trustee of the museum should defend members of the museum staff from supposedly (but imagined) personal attacks at the celebration of the museum's centenary. The issues raised are not, however, irrelevancies, even if not all of them are relevant to the museum. The defence would have been more persuasive if there had been less of it. And it was unfair to suggest that Nature's interest was by sensation to enlarge its circulation.

In all the argument of the past several months, perhaps the most important issue has been curiously neglected. Like many other invaluable institutions, the Natural History Museum is staffed by scientists who are public servants. This circumstance is not usually restrictive. Members of the museum's staff ordinarily function as

scholars without impediment. On the question of the public policy of the institution for which they work, however, civil service employees are less than free. In the past several months, many among the museum's staff have sympathized with many of the complaints made against their institution, but have been gagged. The problem is not novel. Scientists working in defence establishments may, for example, differ from official policy on defence procurement, but may be unable to say so publicly. Those working on the development of the Anglo-French supersonic aircraft Concorde may have considered at the time that the project would be a waste of money and resources, and would by now have been justified by events. In such circumstances, however, it is understandable (if reprehensible) that laboratories should require their employee-scientists to keep their silence. The case for insisting on such a policy at an institution such as a natural history museum, whose public reputation stems from the supposed academic independence and integrity of its members, is by comparison non-existent. It is to be hoped that the museum's trustees will now give this problem the attention it deserves, and urgently. For the correspondence of the past months shows that there is a great depth of seemly and legitimate professional interest in Darwinism, cladism and related matters. And it is not long until next April, when it will be time to mark the centenary of Charles Darwin's death.

Too much government

The British government has once again slipped into the trap of taking too detailed an interest in the management of technology, this time in the development of the British nuclear power programme. Last week, the Department of Energy published its reply (see page 398) to the Select Committee on Energy's report which, among other things, advocated that attention should be paid, even at this late stage, to the building of heavy water reactors on the Canadian pattern. In doing so, the committee was keeping faith with the traditions established by its predecessors (principally the now defunct Select Committee on Science and Technology) in hankering after reactor designs that nobody with direct responsibility for generating electricity wants to build. (Nearly a decade ago, the committee was pushing for the steam generating heavy water reactor, a complicated device using heavy water as a neutron moderator and pressurized ordinary water as a coolant, which was in 1977 discovered to be too complicated to fabricate.)

The Department of Energy rightly said last week that nothing has happened in the past four years to suggest that Canadian heavy water reactors would be economic in British circumstances, and thus rejected the committee's chief technical recommendation. As the department responsible for the Central Electricity Generating Board, the principal owner of reactors in the British electricity supply network, the department is well within its rights in making this opinion public. But it goes too far when it declares that the next thermal reactor ordered for the British network "should be the Pressurized Water Reactor". By this declarative statement of technical policy, the Department of Energy has committed the British government not merely to a technical policy that it (or its successor) may regret, but to a role in the management of technology that it should not be playing.

The circumstances are clear. The nationalized industry with a near-monopoly right to generate electricity south of the Scottish border is the Central Electricity Generating Board, much criticized by the Select Committee on Energy for its overoptimistic forecasts of electricity demand and for its imprecise calculations of the relative costs of generating electricity from different fuels. Constitutionally, the board has an unambiguous technical responsibility for deciding how best to generate electricity. If, with the passage of time, the board is found to be incompetent, either technically or in its economic judgements, the Department of Energy has a right, even a responsibility, to fire the board and appoint another. But if the department also sets itself up as the body that decides what kinds of reactors should be built,

its freedom to exercise its own constitutional responsibilities must be compromised. Worse, the government itself, and not the generating board, will become the target for the torrent of complaint that will be mobilized at next year's public inquiry at the proposal to "recreate Three Mile Island in Suffolk" (for where the generating station is destined). The result will be that the government's essential quasi-judicial role as the arbiter between the generating board and public protesters will also be undermined. How can it be otherwise when the department in its reply to the select committee uses forms of words such as "the government believes" that the next British reactor ordered should be a pressurized water reactor?

This complaint is not mere pendantry. Forms of words matter, and in this case all too clearly reveal that the Department of Energy has not clarified for itself its relationship with the electricity-generating industry. The result is that the department's announcement of the form of the public inquiry about the first British reactor of this type has a hollow ring. Last week's document says that the inquiry is to be "wide ranging", that documents describing the studies that will have been made of the safety of the British reactor should be published well in advance, and that objectors should have time in which to prepare their case. The department rejects the select committee's proposal that a time limit should be fixed for the inquiry. All this is sensible enough if the objective is to reconvert British public opinion to nuclear power. The snag is that the department, having announced in advance its "belief" in the generating board's plan, will be accused at the inquiry of being a prejudiced judge in the case. This is a surprising error for a government which, at its election two years ago, advocated that government should be less obtrusive.

Over-civil servants

The trouble with the British government's response last week to the inter-departmental review of the scientific civil service published nearly a year ago (see Nature 287, 264; 1980) is that much of what it says has been said before. Yes, steps will be taken to help people recruited into the public service as scientists to move to administrative work. Yes, arrangements will be worked out to make the careers of those who stay as working scientists more interesting and challenging. Yes, steps will be taken to see whether government departments could make fuller use of scientists on short-term appointments. Yes, steps will be taken to define the roles of chief scientists in government departments (and then to ensure that these roles are carried out). Yes, steps will be taken to improve the literature handed out to potential recruits to the British scientific civil service (and departments will be asked to explain themselves to the Civil Service Department if they make a habit of recruiting highly qualified people to relatively lowly jobs). Yes, yes; the future will indeed be different from the past and better, more enlightened, more flexible, more challenging.

Brave words do not necessarily come true, as the negligible response of successive governments to the report of Lord Fulton's Royal Commission on the Civil Service more than a decade ago has shown. Briefly, however, the British civil service (and any other public service) has two overriding problems to solve in its relationship with scientists. First, how is the appalling lack of scientific understanding in the formulation of general policy to be made good? And how are those employed exclusively as scientists to be kept interested and alert? The simplest course would solve both problems. Let the recruitment of professional scientists (PhDs for example) to the public service be at the outset for an initial period of seven years. Let it be understood that those dispensed with at the end of this period are given a substantial gratuity, say a year's salary. And let it be understood that those kept on should either help to make policy or function as professional scientists, with the proviso that while they may be required confidentially to advise the departments that employ them on technical matters, they should be free to take part in the affairs of the intellectual professions that gave them skill (see above).

US industry moves into biotechnology

Du Pont sets up new lab, others to come

Washington

Reluctant to commit themselves to the commercial promise of the "new biology" only a few years ago, the United States chemical giants are now queuing up to jump in the deep end. Last week the largest of all, Du Pont, announced plans for a new \$85 million life sciences complex, designed for 700 scientists and technical personnel, to be built near the company's headquarters in Wilmington, Delaware.

One of Du Pont's closest rivals, Monsanto, has already established what the company describes as a "free-standing molecular biology center", which will have "a larger component of basic research than at most industrial companies". According to Monsanto chairman, Mr John Hanley, genetic engineering is likely to become a major branch of the company in the future; "we're up to the eyeballs in molecular biology", he says.

Both companies already have substantial contracts with outside research institutions. Last month, for example, Du Pont announced a five-year, \$6 million agreement with Harvard Medical School (see Nature 16 July, p. 191) to conduct research on molecular genetics, with the company receiving exclusive licences to market any resulting products. Monsanto signed a similar deal with the same institution, though with a slightly different focus, six years ago; recently it has been working with Genentech on bovine and porcine hormones, looking at ways of producing more meat with less feed.

At the same time, however, major chemical companies such as Du Pont and Monsanto are building up their in-house capacity at a rate which is already producing major recruitment difficulties.

Du Pont's life sciences complex is part of a plan to raise from 10 to 20 per cent the proportion of gross revenues which the company earns from sales of pharmaceutical, biomedical and agricultural products. According to the company's new chairman, Mr Edward Jefferson, it intends to spend 21 per cent of its \$570 million research budget next year on the life sciences, and that figure is expected to increase over the next five years.

The new complex will include a 250,000-square-foot facility for health sciences research and a 100,000-square-foot expansion of existing plant laboratories at the company's experimental station in Delaware. Completion is

scheduled for December 1983, and the company intends to expand the scope of current research not only in molecular genetics, but also in fields such as immunology, neurobiology, cardiology, gerontology, plant biology, plant pathology and entomology.

Du Pont's announcement seems to have been partly precipitated by rumours that the company's current attempts to take over the oil company Conoco could interfere with Du Pont's recent moves to diversify away from petroleum-based products. Mr Jefferson has denied such rumours, claiming that the company intends to continue its aggressive thrust into the life sciences for their own sake—and for the profit they may bring.

Several petroleum companies are themselves beginning to enter the fields. Atlantic Richfield has set up a genetic engineering laboratory which company officials describe as "our most academic laboratory"; novel arrangements being discussed include two-year research appointments, and lengthy sabbaticals for research workers who wish to spend time at universities.

Waiting in the wings is the Exxon Research and Engineering Company, the research wing of Exxon Corporation, with an annual research budget of \$489 million—almost half that of the National Science Foundation. Company officials declined

to comment last week on the company's plans, saying that no announcement was expected for several months; however, there are rumours that Exxon is working on an arrangement that it likes to compare with the position of the Bell Laboratories in telecommunications research.

The broad potential impact of life sciences research in medicine is revealed in a report, entitled *Forecast of Emerging Technologies*, soon to be released by the Food and Drug Administration, of a study in which 190 experts both inside and independent of the agency were asked to predict which new medical technologies were likely to emerge within the next fifteen years.

Almost a quarter of the 168 technologies listed involved basic areas of genetic engineering and computer technology. Eight technologies accounted for one-third of the citations, headed by hybridoma technology, nuclear magnetic resonance imaging and the use of recombinant DNA to produce interferom.

Meanwhile at least one university has decided to provide financial support to faculty members attempting to exploit the result of their research in molecular biology. The Michigan State University Foundation has announced that it is contributing \$100,000 to help set up a new company, called Neogen, which is expected to specialize in the genetic engineering of plants.

David Dickson

Research council plans academic rescue

Britain's Science and Engineering Research Council is to come to the aid of outstanding academics threatened with redundancy as a result of cuts in the universities' income. Last week, the council decided that it would help academics in departments marked for closure to transfer to other universities, and would pay their salaries for up to ten years if necessary. The council is calculating that the universities should then have reorganized themselves and that the University Grants Committee should be able to take up the bill again.

The council is particularly anxious that good individuals and groups should not be lost simply because they happen to work in those universities faced with the largest cuts in their income. It will be looking for academics that it considers especially valuable who are about to lose their jobs and may also consider setting up special transfer fellowships for which threatened academics will be eligible to apply.

As yet, the council has little idea of how many individuals it will want to support or how much money it should set aside. Estimates will have to wait at least until the autumn, according to Sir Geoffrey Allen, chairman of the council, when universities have a better idea of where economies will fall. In the meantime, the council has increased the number of replacement

fellowships, by which a senior academic returns to research leaving a tenured post for a younger person, from 15 to 20 per year. The council, which will pay the net cost for five years, expects to spend £500,000 a year on the scheme

Sir Geoffrey's main concern is that the cuts in university income will further undermine the dual support system for research, whereby the University Grants Committee provides funds for staff and well equipped laboratories and the research councils award grants for specific projects. The gradual undermining of the universities' income over recent years has already weakened the research base, according to Sir Geoffrey, who is anxious that the restructuring of the university system caused by the cuts should be designed to strengthen the research base to near its former level rather than weaken it further.

He would like to see individual universities concentrate their efforts to a greater extent than implied by the University Grants Committee in its advice to them, preferring a smaller but stronger research base to a larger, weaker one. Although those views are shared by the University Grants Committee, which has attempted to confine the misery caused by the cuts by being selective, Sir Geoffrey believes that the selectivity could and should go further.

Judy Redfearn

French universities

Decision postponed

The 74 French universities, many of them created in the reform which followed the student rebellion of 1968, are in suspense. Does the new Socialist government love them or not?

The Minister of Education, M. Alain Savary, is keeping his own counsel. He has received representations from all sectors of the universities, from unions to presidents, since his invitation to the universities to appeal against the recently-published list of habilitations — a list of qualifications that each university is allowed to offer. The list was conceived largely by the previous Giscardian minister, Mme Alice Saunier-Seité, and eliminated many old courses and refused the introduction of some new ones. A second, supplementary list was promised for last Saturday — but it did not materialize.

Now, says the ministry, it will appear at the beginning of August, when conveniently most of France is on holiday. And at the end of the vacation, M. Savary is to call unions and university presidents to a discussion, where he will attempt to reach agreement on new rules for creating university research and teaching programmes.

The implication may be that the new list will not be everything the universities want — which is approval for all the courses they propose. For defying Savary's call for self-restraint, the universities have thrown themselves solidly behind their original lists, so heavily pruned by Saunier-Seïté.

Nevertheless, they could have done little else, for Savary has given them no guidelines for what to keep and what to cut.

In the end, it may be the level of political pressure that has been brought on him that will determine which courses are approved. For example, at the Université de Haut-Bretagne (Rennes II), it appears that a course on the Breton language will be restored in the second list because of pressure from a group of Breton parliamentarians. After all, the government is pledged to respect and increase regional autonomy. And the new emphasis on the oceans (France has for the first time a minister of the sea) may save a course of oceanography at the Université de Toulon et du Var.

Savary certainly declared himself appalled at the state of university politics when he arrived in office, and it has not all been attributable to his predecessor. According to one senior scientific official, the university system had got out of hand after 1968, and needed to be trimmed. Ninety-five per cent of Saunier-Seïté's cuts were well judged, he thought.

However, such outspoken officials and heads of department may find themselves the symbolic sacrifices of the new government, to satisfy the multitude while the new politics is being thrashed out. At the beginning of this month, one of the teaching unions (SGEN-CFDT) called for the resignation of certain heads of department who were still actively supporting Saunier-Seïté's point of view; and now it seems the Council of Ministers has a list of 27 names before it. These counterrevolutionaries may have to go, it is implied.

Robert Walgate

UK nuclear energy

Maintaining course

The British government remains convinced of the wisdom of its nuclear policy in spite of criticism from the House of Commons Select Committee on Energy in a report published earlier this year (see Nature 19 February, p.621). In a reply to that report, released last week (Nuclear Power, Cmnd 8317, HMSO, £2.30), the Department of Energy reiterates its belief that Britain could need 20 GW of new electricity generating capacity by the year 2000 and should go ahead with the programme, outlined in 1979, to order one new nuclear reactor a year for the next decade (15 GW in all). But it agrees with the select committee that the programme should be flexible and that each new order should be assessed on its merits.

The government is, however, sceptical of the select committee's suggestion that the £15,000 million that the programme is expected to cost might be better spent on conservation, saying that the relative benefits of investing in new plant and in conservation are too difficult to estimate. But it has accepted the recommendation that the planning margins of the Central Electricity Generating Board (CEGB), 28 per cent, should be reconsidered and has charged the Electricity Council with the task. On the contentious question of estimating future electricity demand, it says that it must rely on its own estimates and those of the Central Electricity Generating Board, the latest of which assume a growth rate in the economy of 1 per cent a year until the end of the century. Some of the estimates are due to be updated.

The select committee was particularly disturbed when it came to assess the nuclear programme on economic grounds. It shared the concern of a subsequent Monopolies and Mergers Commission report on CEGB over the way the board has estimated future capital costs from historic costs. The government agrees that this is an unreliable way of appraising future investment and, taking its cue more from the Monopolies Commission than from the select committee, has asked CEGB for improvements in its investment analysis. It has also asked for reassessments of assumptions about future coal prices and availability, power station construction times and costs and the performance of advanced gas-cooled reactors.

No change is planned, however, to the

structure of the nuclear power industry, nor does the government intend to implement the select committee's recommendations for broadening its advice on nuclear matters. But the Secretary of State is already looking at ways of attracting suitable staff to the Nuclear Installations Inspectorate.

The government is still set for a public inquiry in 1982 into the siting of Britain's first pressurized water reactor, intended to start off the new programme, at Sizewell in Suffolk. Although the precise details of the inquiry have yet to be released, Sir Frank Layfield, QC, who chaired an inquiry into local government finance in 1974, was appointed its inspector last week. The government will not, however, expect the inquiry to examine the merits of the pressurized water reactor relative to CANDU, the Canadian heavy water reactor. It rejected the select committee's recommendation for an urgent new appraisal of CANDU on the grounds that the costs of adapting it to British conditions would be too high at this stage.

Judy Redfearn

Science education funding

Pressing claims

Washington

In one of his first acts as the new president of the National Academy of Sciences, Dr Frank Press, formerly director of the Office of Science and Technology Policy under President Carter, has strongly criticized the cuts in federal support for science education that have been proposed by the Reagan Administration.

Dr Press's comments on the proposed cuts, which would virtually eliminate funding for science education from the National Science Foundation (NSF), were contained in a letter to the chairman of the House of Representatives Science and Technology Committee, Mr Don Fuqua. And the letter, together with similar complaints voiced by individuals and instituions from across the country, seems to have had an effect.

Last week, the House voted to approve a 1982 budget for NSF which included an additional \$35 million for science education in excess of the Administration's request. In the process, the Democrat-controlled body rejected by 264 votes to 152 an attempt by Republicans to remove this extra money from the NSF appropriations bill and reduce the foundation's total budget to the \$1,033 million proposed by President Reagan.

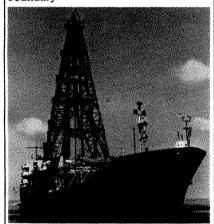

Although the House vote may prove to be critical in restoring the science education funds, there is still some way to go. Also last week the Senate appropriations committee approved a budget of \$1,044 million for NSF, which includes an additional \$20 million for science education; if accepted by the full Senate, the subsequent compromise with the

House would lie between this and \$35 million.

In his letter to Mr Fuqua, Dr Press points out that a study carried out last year for Mr Carter by NSF and the Department of Education demonstrated problems caused by the deterioration of science and engineering education that "are pervasive and complex and will require determined and concerted effort by all sectors of society for their solution". David Dickson

A brief respite

The Glomar Challenger, the work-horse of the Deep Sea Drilling Project, docked last week at Southampton in preparation for the next stage (Leg 81) of the project. The previous leg was spent in the Bay of Biscay, to determine the rifting and subsidence history of the continental margin. Leg 81 will be spent near Rockall, a few hundred miles to the west of Scotland, studying the variations of subsidence across the ocean-continent boundary.

Challenger on the crest of a wave

The Deep Sea Drilling Project is at present riding on a wave of enthusiasm for its scientific record, and has so far done well in President Reagan's financial obstacle race. Glomar Challenger's drilling operations are funded for at least another two years, with a 1982 budget of \$26 million. Of this, \$12 million will come from Britain, Germany, France, the Soviet Union and Japan, while the bulk of the United States contribution will be provided by the National Science Foundation.

Future plans are, however, less certain because of the debate within the foundation over the competing merits of Glomar Explorer - the converted ex-CIA submarine-dredger. Although vastly more expensive (its expected cost lies between \$500 million and \$1,000 million over ten years), the Explorer programme would be half financed by the oil industry on the strength of its considerable oilhunting potential. The scientific issues are complex, however; and a decision from Congress on whether or not to fund initial Explorer development is expected Philip Campbell in October.

EEC hormone legislation

First another report

Brussels

Progress of a sort was achieved by the European Community's agricultural ministers in Brussels last week when they discussed the problem of a total ban on hormone use in livestock breeding. They decided that Community law should ban stilbenes and thyrostatics as growth promoters in livestock breeding even though these hormones are already outlawed in all the member states.

And to serve as a figleaf for the lack of agreement on other growth promoters, it was decided to wait for a scientific report before dealing with the natural hormones oestradiol, progesterone, testosterone and the synthetic hormones trembolone and zeranol. A deadline of nine months has been set for this report but quite how it will help to solve what is essentially a political problem nobody is quite sure.

Details of how this scientific report will be compiled are also still hazy. Presumably, the same national experts who form the various scientific committees advising the European Commission on veterinary or nutritional matters will assess the present state of knowledge.

European consumer groups are planning to write to their ministers to demand that these experts are chosen for their impartiality. In fact, anyone nominated by a national government will have already contributed towards that government's position on hormones. The scientific report may therefore end up reflecting only the existing divisions of opinion.

The United Kingdom and Ireland are the strongest opponents of a blanket ban, but producers in other member states are lobbying effectively in the other direction. France, Denmark and Italy want legislation to be as severe as possible — and it was the ruling of an Italian court to ban veal sales which started the whole affair. The new French agriculture minister, Edith Cresson, stressed at the Council that France would not be bound by the conclusions of the scientific report. Belgium and Germany in theory already ban the use of all hormones.

Consumer groups are also incensed by the ministers' reluctance to thrash out the ways and means to enforce a ban of any kind. Natural hormones are notoriously difficult to detect and the various member states do not all have the same reputation for the effective policing of detectable substances.

What has been achieved is the right for any member country to prevent the entry from another EEC country of meat which contains hormones such as stilboestrol, diethylstilboestrol, dienoestrol and hexoestrol. And those member states with legislation which bans other hormones can carry on as before.

In nine months' time, the European

Community will still have to decide between a policy which favours the consumer approach of banning unless proved safe and one favouring the industry's attitude of carrying on until a substance is known to be dangerous to human health — which is the choice of the United States.

Jasper Becker

Third World development

Proper priorities

Washington

The US Agency for International Development (AID) is continuing to pick up the pieces following the failure of the Carter Administration to convince Congress of the need for a new Institute for Scientific and Technological Cooperation to act as a focus for research on the needs of Third World countries.

Earlier this month the agency announced that as part of a general reorganization, a new Bureau of Science and Technology was to be established. Furthermore the title of "assistant administrator for development support" will be changed to "senior assistant administrator for science and technology", a position that will have responsibility for the bureau.

One of the aims of this reorganization, according to agency officials, is to strengthen the research activities of AID which have in the past been of lower priority than more conventional technical aid programmes. This was one of the reasons quoted for establishing the Institute for Scientific and Technological Cooperation, a body which would remain under the same umbrella as AID, but operate independently with its own board of advisers.

The parallel between the goals of the ill-fated institute and the newly proposed bureau is strengthened by the fact that Mr Reagan's appointee to head the bureau, Dr Nyle Brady, had previously been successfully wooed by the Carter Administration as its proposed director for the institute. Dr Brady will have responsibility for the administration of a wide range of centrally-funded research and development programmes, some of which were to have been shifted from AID to the new institute.

The Carter Administration had originally proposed significant increases in research support for these areas which would have virtually doubled the AID budget for research and development to \$229.8 million in the fiscal year 1982. The Reagan Administration has reduced this dramatically to a request for \$134.5 million, with large cuts, for example, in support for agricultural research on food production in Africa.

Even with these cuts, however, AID officials point out that the Administration's request for science and technology programmes for 1982 is 40 per cent higher than the amount spent on

research by AID in 1980. A particularly significant increase is in energy research, scheduled to grow from \$3.4 million in 1980 to \$16.3 million in 1982.

The impact the increase in funds and the internal reorganization will have remains controversial. Those in Congress who argued most strongly for the institute are somewhat sceptical.

This scepticism is reflected in a report from the House Foreign Affairs Committee on the AID budget request, which has included as a separate item a proposed \$10 million (reduced from President Carter's requested \$18 million) for the support of scientific and technological cooperation with developing countries. The committee has reinserted this money into the broader category of "selected development activities".

In fact, much of this money will be spent in a way comparable to what the institute would have done, but through a different agency, the National Academy of Sciences. AID has agreed to provide \$35 million of its science and technology funds over the next five years to a new grants programme established under the academy's Board on Science and Technology for International Development.

The grants, which will be \$5 million for 1981 and increase to \$10 million by the middle of the decade, will be spent largely on supporting research activities in the developing countries on projects selected by an advisory board. "One of our principal goals is to help developing countries build up their research capabilities, precisely the request that they were making at UNCSTD (the United National Conference on Science and Technology for Development) in Vienna in 1979", says the board's staff director, Dr Victor Rabinowitch.

When the grants programme is added to its more traditional activities, such as arranging seminars on Third World problems, the board will begin to resemble a scaled-down version of the Institute for Scientific and Technological Cooperation.

Furthermore its relative autonomy from AID goes some way to meeting the objections of those who argued that, as put forward by the Carter Administration, the inclusion of the institute under the umbrella of development aid bodies would have stifled its flexibility. David Dickson

Polish economic reform

Self-governance wins

Warsaw

The latest Polish plans for economic reform, discussed in considerable detail during the recent extraordinary Party congress, include a major shake-up for Polish science and technology. The basis of the proposed new economic model is a switch from rigid central planning of industrial production to a degree of "selfgovernance" (samorzadność) - a word introduced into the Polish political lexicon

with the rise of the independent trade union movement last August.

The new system, which is to be introduced in four phases over the next 18 months, will allow for more public and expert discussion in advance of overall production plans and delegate to factories initiative for deciding how they fit in with the overall targets.

As in Hungary, the authorities will steer production by a system of financial incentives, but factory managements will have considerable responsibility for decision-making on modernization and technological innovation. One of the major charges laid against the previous Gierek government in the preamble to the new plan is that autocratic planning blocked technical innovation. At the same time, many of Mr Gierek's prestigious schemes are being dropped. The "Program-Wisla", for example, which was totally to remodel Poland's major waterway by the end of the century, has been cut back to its environmental and agricultural components. The schemes for hydroelectric dams and the straightening of rivers have been dropped sine die.

Other harm done by Gierek's policies will not be so easily remedied. Discrimination against the private farmer in the pricing and supply system ran agriculture down to a level where even the new rationing system cannot ensure supplies of basic home-produced foods. The abolition of the small pharmaceutical cooperative factories in the 1970s has meant that Poland has had to shop abroad for a wide variety of drugs whose production runs were too small for the state pharmaceutical enterprise Polfa - and when hard currency ran out, so did the supply of even the most essential drugs. The international relief operation to ensure vital supplies now being mounted jointly by Solidarity and the Polish Ministry of Health is a strange contrast with the anxiety in the mid-1960s in the United Kingdom that Polish drugs might undercut the domestic products.

Although the new plan pays lip-service to the strengthening of scientific and technical ties with other (especially Comecon) countries, it is also clear that for the present Poland will have to rely mainly on homebased technology.

A reorganization of the responsible ministries is also on the cards. One is for a State Committee for Technical Progress responsible to the Prime Minister. The new body would be unique in the Comecon bloc in dealing only with technology, and may point to an ultimate break-up of the Ministry of Science, Higher Education and Technology. Straws in the wind include the appointment last month of a mining specialist, Jerzy Nawrocki, as Minister of Science, Higher Education and Technology, and the plans discussed at the congress for a complete review of the country's industrial research institutes and the closure of those not cost effective.

Whatever the final form of the reorgani-

zation, one change is certain — a revision of the present practice of financing science by "problems" ostensibly related to economic needs and organized into a cumbersome hierarchy of priorities. Among likely innovations are direct research contracts between industry and the universities or academy institutes and the allocation of funds for basic research directly to the institutions concerned.

For the moment, however, virtually all such funding will come in non-convertible zloty. Hard currency for the purchase of equipment, reagents or journals from the West is simply not to be had; according to one leading physicist, only two subscriptions to Nature are now authorized for the whole of Warsaw.

British Technology Group

Mixed marriage

Last week, Britain's National Enterprise Board and the National Research Development Corporation finally merged. The British Technology Group, as the two are now called, has been in the offing since Sir Frederick Wood was appointed chairman of both the board and the corporation at the beginning of the year. His plan for a merger has now been accepted by the government, although legislation to give the group formal status will not be possible until 1983.

The plan is that the group will offer more streamlined services to innovators seeking backing for their ventures than either of the parent organizations. The merger will also eliminate competition between the board and corporation for the same projects.

The function of the former corporation to support research and development into potentially marketable innovations will be largely taken over by the group's technology transfer division. And the board's experience in raising finance to invest in industry will be incorporated into the new investment and operations divisions, the latter being responsible for returning investments to the private sector.

Both parent organizations have been widely criticized in the past. The board, which was originally set up in 1965 by the then Labour government with the potent title of Industrial Reconstruction Corporation, has since been substantially curtailed. And the corporation has been criticized mainly by academics for not being adventurous enough in supporting their innovations and persuading industry to take them up. The British Technology Group is intended primarily to marry the corporation's access to innovators with the board's financial expertise. There is to be a new liaison team whose prime responsibility will be to scour the universities more aggressively than in the past.

The group is also to have a new corporate development unit to develop strategies for investment. Areas of priority are advanced manufacturing and biotechnology. A

study team on robotics has already presented a strategy paper to the group which is expected to result in investments within the next few months. The group also has plans for investing in biotechnology in areas not covered by Celltech, the company set up by the board last year.

As yet the group does not know precisely how much public money it will have to spend. The precise structure of the new organization should become clearer in September.

Judy Redfearn

Tidal energy

The big dam

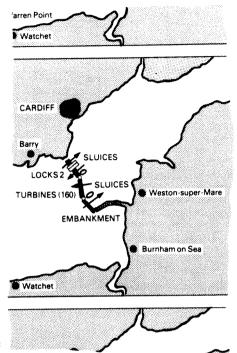

The economic feasibility of a tidal barrage for generating electricity across the Severn estuary in south-west England will depend on how many nuclear power stations are attached to the national grid. In most circumstances, however, a barrage would be a good investment, according to a report by the Severn Barrage Committee published last week. The committee, set up in 1978 under Sir Hermann Bondi, then chief scientist at the Department of Energy, and whose deliberations have cost £2.3 million, has also concluded that a barrage is technically feasible but has called for detailed studies of its potential environmental, industrial and social impact.

The outlook for a barrage across the Severn estuary, which has one of the greatest tidal ranges in the world, has improved considerably in the past two years, according to the committee. Approximately 40 per cent more energy should be obtainable from an inner barrage, the scheme favoured by the committee, than was originally thought. And electricity generation should be possible nine rather than 16 years after the start of construction.

The committee estimates that the most cost-effective scheme would cost about £5,600 million and would generate 13 TWh a year from an installed capacity of 7,200 MW. That scheme is for an inner barrage from Brean Down to Lavernock Point consisting of large prefabricated concrete units housing turbines and sluices. A more ambitious barrage built further out to sea, costing £8,900 million and generating 20 TWh from 12,000 MW capacity, would be less economic and involve greater risk during construction. The inner barrage scheme, on which the committee has based most of its calculations, has the added advantage that a second barrage could be added at a later stage. The two together would provide as much energy as the outer barrage at a similar overall cost.

Because of the variability in tidal energy, a barrage would reduce the need for other generating capacity only by about 1,000 GW, according to the committee, most savings being in fossil fuel. And as nuclear power is also capital-intensive and low on fuel costs, the attractiveness of a barrage will to a large extent depend on future plans

for nuclear power. Under the Central Electricity Generating Board scenario, which assumes a fairly rapid growth in nuclear power stations, the barrage is marginally unattractive, says the committee. But it could provide an attractive alternative if nuclear plans are modified only slightly.

The committee seems convinced that a Severn barrage should at least be seriously considered as a possible alternative to investment in nuclear power. Before a decision is finally taken, however, it recommends further studies of the effects on water levels, wildlife and local amenities and the capacity of British industry to cope with such a project. If the government decides to take investigations further, the next step should be an acceptability and preliminary design study costing £20 million and the building of prototype concrete units at a cost of £25 million.

Judy Redfearn

US nuclear weapons

Lasers purify

Washington

A Washington environmentalist group is trying to prevent the Department of Energy from carrying out an expanded programme of research into laser isotope techniques for separating plutonium for US nuclear weapons from spent nuclear fuel.

A classified research programme into laser isotope separations, using copper vapour lasers for uranium enrichment, has been carried out at a relatively low level of funding at the Department of Energy's Lawrence Livermore National Laboratory and the Los Alamos National Laboratory since the mid-1970s — in both 1980 and 1981 total funding for the programme was \$5 million.

In testimony before a congressional committee in March which has just been declassified, the Department of Energy requested an increase in funds to \$155 million over the next three years to support this research and its application to plutonium enrichment. This money would include the construction of a pilot plant, and the department is also discussing plans to construct a \$200 million multipurpose plutonium isotope production plant.

In a letter sent last week to the Secretary of Energy, Mr James Edwards, a staff scientist and an attorney with the Natural Resources Defense Council say that the plutonium laser isotope separation programme "carries grave nuclear weapons proliferation risks" and is "totally inconsistent with the fundamental objective of President Reagan's nuclear non-proliferation policy".

They point out that although the department has identified several other applications for the process — such as the enrichment of fuel-grade plutonium as fuel for the breeder reactor research programme — "it appears that these applications would not serve as adequate justification for the program, particularly in light of the severe proliferation dangers".

In their presentation to the congressional committee, Department of Energy officials said that the purpose of the expanded programme was to make available for weapons use approximately 70 tonnes of plutonium by reprocessing commercial spent fuel and then enriching the plutonium to weapons-grade by laser isotope separation. It would be possible to convert fuel-grade plutonium produced by the department's nuclear reactor in Hanford, Washington, to weapons-grade.

One of the purposes of the laser isotope separation process is to enrich plutonium to weapons grade by reducing the concentration of the major contaminant isotope Pu-240, which is not spontaneously fissile. According to testimony given to Congress by F. Charles Gilbert, assistant secretary for nuclear materials at the Department of Energy, plutonium is placed in one of four categories depending on the concentration of the Pu-240 contaminant: reactor-grade for 19 per cent or greater, fuel-grade for between 7 and 19 per cent, weapons-grade for less than 7 per cent, and supergrade for between 2 and 3 per cent.

The laser enrichment process has two non-military uses. The first is the separation of the Pu-238 isotope, which is used in space satellites and heart pacemakers, as well as for a heat source in thermoelectric generators. The second is the separation of the Pu-241 isotope which decays to Am-21 which is used in smoke detectors and for logging wells. According to the Department of Energy, the non-weapons applications at present require less than two per cent of the output of the Savannah River plant, which is the current source of supergrade plutonium.

David Dickson

CORRESPONDENCE

Man versus tsetse

SIR - I must contend with your leading article "Fighting tsetse flies and people" (Nature 2 July, p.1).

In it you state that the eradication of the tsetse fly in certain parts of Africa (by such organizations as ILRAD) would be a revolutionary advancement for its people. Cattle would then be able to graze over a much larger area of land, so more food would

This, in itself, is quite true — for man. But the tsetse fly is one of the last remaining barriers against mankind's inevitable destruction of the natural habitats for literally millions of animals of the continent. Would not this "advancement" seal the fate of these millions?

Animals in the wild cannot compete with organized grazing. It's like asking one man to stop a moving steamroller by standing in front of it — he would be crushed. The question is: do we have the right to do this, to crush other forms of life?

As the most powerful animal on this planet, man is entrusted with a duty to preserve that which cannot defend itself. Although the African lion is strong, it can't stop a steamroller.

ADAM J. BECKER

Jamesville New York, USA

Author — Anon

SIR — Drs Gillman and Lichtigfeld (Nature 25 June, p.608) suggest that the present system of assessment of scientific papers is endangered by a cabal of corrupt referees, and propose a completely open system. Referees may be prejudiced and incompetent but they are not a secret society. Vigilant editorial control rather than public exposure seems the most appropriate way to eliminate bad referees.

Since referees may be influenced by the known standing of the author or the author's institute. I propose that the anonymity afforded to referees should be extended to authors. If papers were submitted with the author's name, address and acknowledgements on separate sheets of paper and these were retained by the editor when the manuscript was forwarded to the referees, conscious or unconscious bias would be avoided.

P.M. GAYLARDE

From the museum

Sir - We should like to explain a matter that puzzled you in your editorial of 2 July (p.1): the place of cladistics in the exhibition policy of the British Museum (Natural History).

Exhibitions have a general tendency to conceal background controversyl. This should not be seen as a conspiracy on the part of designers but is, in fact, a phenomenon that is apparent in the majority of educational media. Every lecturer or textbook writer has to decide the extent to which he will emphasize a straightforward story at the expense of alternative views. The emphasis chosen depends on the circumstances; the less

knowledgeable the audience, the less appropriate it is to elaborate the story. Knowing how to make this choice is particularly difficult in exhibitions since the limits of educational attainment are even less well understood than in other more generally practised media. In public museums there is an overriding need "to deliver an interesting and stimulating message to laymen"2

One of the essentials for good communication in a museum is to set objects within some kind of context so that specimens take their place in a coherent line of thought and do not seem to be a series of unrelated items. Without such a context, the specimens have little meaning and odd facts that are gleaned tend to be quickly forgotten; in educational terms, the exhibit would be a failure.

In two of our recent exhibitions, Man's place in evolution and Dinosaurs and their living relatives, the context for the specimens has been that of phylogeny and the fact that we chose to present phylogeny in cladistic terms has been seen by some critics as an attempt to promote cladistics at the expense of more traditional views. Recent correspondence in Nature and elsewhere emphasizes the fact that a heated debate is in progress about the relative merits of cladistic and traditional approaches to phylogeny and systematics. Exhibitions have no part in this debate between scientists, but it is clear that whichever system is used in an exhibition, one faction or another will be provoked into stern response. Accepting that one of the competing systems had to be chosen, we judged on educational grounds that cladistics was the most appropriate because of its clear and overt reasoning. Once a layman has been introduced to the system he is in a better position to understand why and how the scientists reach their conclusions. No one would pretend that the use of a cladistic system makes the study of phylogeny easy, but it can make the steps in the argument more apparent.

Some critics feel that the exhibitions should have said more about the existence of alternative systems and we are making some changes to meet that criticism, but the danger is that the exhibits in question may become displays about phylogenetic systems rather than about fossil man, or dinosaurs. A separate exhibition about systems of classification which is scheduled for future display may help to give a fuller presentation of current views.

The recent controversy has highlighted how difficult it is to maintain a balance in exhibitions between directness and fairness to every point of view - exhaustive can be exhausting to the visitor. The application of educational principles to museum exhibitions is a subject that has been sadly neglected in the past and the credibility of museums as a means of informal education has suffered in consequence. We should like to encourage serious discussion and research in this field.

Suiting everyone

SIR - You object most strongly (Nature 12 March, p.75) to the phrase "If the theory of evolution is true . . .". Having myself tried more than once to explain the work of a scientific institute in everyday language, I have some sympathy with the author of the museum guide. When all is said and done, scientific knowledge is provisional and fallible, as, implicitly, you agree. Your objection seems to be that this particular form of words gives a handle to those opponents of evolutionism whose views you regard as not "respectable". specifically to creationists. I am not a creationist and accept the evidence that evolution by natural selection has taken place. ultimately producing Man. Nevertheless I sometimes find biologists, when writing for a popular readership, to be overly dogmatic on this point. The creationist movement on this continent (which is not simply a revival of fundamentalism and obscurantism) is partly inspired, I believe, by a healthy reaction to this dogmatism.

To represent our scientific theories as final when they are not is in the long run to do our own cause a disservice, and is, in any case, dishonest. Can any evolutionist provide a clinching argument that chance mutations acted on by natural selection alone are the mechanism of evolution? I think not, and, indeed, I myself find it at least as easy to believe that there has been a purposive element in evolution. Did you really mean to imply that it is not "respectable" to believe "that the course of events may be determined by literally supernatural infuences"?

In your last paragraph, you almost seem to be proposing a noble myth, the purpose of which will be to keep all us scientists working happily at our research. If we recognize too clearly the logical status of our theories, you argue, the scientific enterprise will be undermined. But Popper's ideas, as you admit, have been around since 1934, and many branches of science have been uncommonly vigorous since then. Your argument has something in common with the old discredited argument that Christianity is socially beneficial and should be taught to the young whether it is true or false. It is this kind of argument that plays into the hands of creationists, by making more plausible their claim that evolutionism is not a scientific theory, but a kind of religion.

The most helpful ideas in this situation, I find, are not Popper's, nor dogmatism, but Kuhn's. Almost all of modern biology is "normal science" within the paradigm of Darwinism-Mendelism. Always there are some facts that do not fit a paradigm, and one day they may become so bothersome we will have to change it. In the meantime, it provides a frame of reference in which we work and by which we make sense of a wide range of data and experience. Darwinism-Mendelism is the best paradigm we have (in its field) and, as Darwin said, gives grandeur to our view of life, but it should not fight its critics by claiming, like them, to be based on divine revelation.

Too tolerant

SiR — I agree with you (Nature 28 May, p.271) that tolerance of religious fundamentalism in the Natural History Museum has gone too far. But you underestimate the menace to science, and to the propagation of rational thinking by education, presented by this tolerance. I see two problems — first the conflict between science, in the broadest sense of the word, and mythology. The second is the egalitarian and anti-elitist attitude prevailing among many educated people which has brought about the woolly-minded tolerance you describe.

Homo sapiens indulges in two main kinds of thinking about his world which must go back to the very emergence of the first intelligent, tool-making primates. The appearance of the first stone tools, adapted for specific uses, implies the existence of empirical thinking involving designing an implement for future use, testing it practically and modifying it in the light of experience. From this technological thinking, based on trial and error, must ultimately have developed scientific thinking, based on observation, hypothesis, prediction, experimental test and modification.

On the other hand myth-making must have emerged at an equally early time to allow primitive men and women to explain the vast range of often frightening phenomena outside their understanding.

We might also describe this duality of thought processes in terms of deductive and inductive thinking. In the former the grand, explanatory ideas come first (usually being taught as dogma) and are then used to interpret everyday natural and social phenomena. In the latter the explanatory general hypotheses are developed specifically to explain a body of facts or phenomena. I am now using the term "myth" to describe all preconceived ideas or beliefs reached deductively (before examining the evidence properly) and "science" to describe the opposing, inductive method of explaining things (which also involves testing the hypotheses devised).

The conflict between these two modes of thought seems to be as basic now as it was in Darwin's time and to have extended into many more fields. Myths are believed in for a variety of reasons, both reputable and otherwise, but it seems reasonable to suppose that they reflect psychological or emotional needs. Their great variation suggests this, the zeal with which they are believed being the only common factor. The dedicated communist, Christian, Buddhist, believer in flying saucers or in a tribal god each believes his creed deductively (usually having been taught it a priori) and each is equally convinced of its truth, and of the folly or evil of those who disagree. The only common factor seems to be a strong, often overwhelming, perhaps unconscious desire to believe in some set of ideas which explain phenomena one is interested in or worried about. This is the exact opposite of the scientific method.

It is essential to realise that what is being described here is a mental attitude and not categories of rational and irrational subjects to think about. Of course it is possible to be a communist or a Christian on inductive, rational grounds if one has studied as much of the evidence as possible, considered alternative explanations for it and found them less convincing. Likewise it is unfortunately true

that a scientist can elevate the status of his favourite theory in his own mind to that of a myth — and believe it implicitly, emotionally and against all opposition. It is the mental attitude, not the subject matter, which produces both myth and science.

It follows that there can be no place for myths either in science or in any proper education programme that tries to avoid indoctrination. "Creation science" is a myth which depends on a dogmatic and deductive faith in the existence of a God who has intervened frequently on Earth to make new living things out of nothing and, this being so, the Natural History Museum may be said to have betrayed both its scientific status and its educational role by implying that this myth is somehow on the same intellectual plane as the theory of evolution.

Where will this process end? Another interesting if minor example of a new myth about human origins appeared in The Sunday Standard of 31 May. A female body builder, when explaining why she pursued this hobby, is reported as saying "We were never meant to be the weaker sex, and being seen as such is a fairly recent evolutionary development. Originally it was women who went out hunting to find food; they were the strength of the family." This relatively harmless myth, though it bears no relation to the facts of archaeology and anthropology, may be assumed to serve a useful purpose to the lady concerned by giving her the comfort of an ideological justification for what most people probably regard as a bizarre hobby. But to the Natural History Museum it must surely now be a valid alternative hypothesis, or even a theory, about the early development of man and society. Perhaps the Public Services Department will consider adding a new panel on "Ms Cheshire's hypothesis" to its display

on human evolution? Or is it the popularity of a myth which qualifies it for serious attention in Cromwell Road now? If so then a panel describing Von Däniken's ideas about the bringing of civilization to Earth by spacemen in prehistoric times is surely required.

My explanation for this excessive tolerance, which is an irresponsible failure to distinguish between scientific thinking and irrational myth-making, is that it is an effect of modern egalitarian thinking. This is quite widespread among some university staff, extending to advocating equal tolerance for the "views" of all people, no matter how well or ill-qualified in the subject concerned. I have actually heard it argued in faculty meetings in this university that it is no longer necessary to have professors as more than administrative departmental heads, to have them leading and guiding their staff in research and academic standards by their example; everyone, it seems, should now be "capable of standing on his own feet". Is this phenomenon sometimes due to a real fear of being thought elitist, "better" than one's fellows, and to a failure to realise that better trained or informed is not the same thing as absolutely better?

It cannot be a coincidence that no equivalents of the "creation science" myth appear in disciplines like engineering or navigation where equal tolerance for them would produce catastrophe. The tolerance of myths about human origins by the staff of the Natural History Museum will not cause their building to fall down about their ears but it has certainly undermined the institution's reputation as an authoritative laymen's guide to the world of science.

E.W. MACKIE

Hunterian Museum, The University of Glasgow, UK

Halstead's defence against irrelevancy

SIR — In his Presidential Address to the British Association in 1977, Sir Andrew Huxley "wondered what topic could, in the second half of the twentieth century, generate emotions as strong as those which arose over evolution in the early 1860s". If the recent correspondence in the columns of *Nature* is anything to go by then it undoubtedly remains this selfsame topic.

Previously I drew attention to what was taking place at the British Museum (Natural History) which occasioned serious disquiet in the scientific community. I suggested a possible explanation, but whether this is rejected or accepted does not affect the substantive issues I raised. So far, no serious attempt has been made by anyone in authority to respond to the accusations that have been levelled.

The present debate began in 1978, when the trend of the new policies of the museum's Public Services Department and the proposed presentation of dinosaurs merely to illustrate cladistics were discussed at a symposium at Reading (see refs 1,2). In 1979 the exhibit "Dinosaurs and their living relatives" opened and the accompanying booklet spelt out clearly exactly what cladistics involved. The crude didactic method of its presentation contrasted dramatically with the popular but nonetheless scholarly approach of the museum's book "A New Look at Dinosaurs" by Alan Charig, published at the same time³.

Then in 1980 came the exhibit "Man's place

in evolution", again with its accompanying booklet in which it was again emphasized that we can never know how species arose in the past and that we assume that new species arise only by splitting from previous species. But the booklet includes the most amazing assertion of all, that no fossil species can be considered the direct ancestor of any other. I referred4 to the place of Homo erectus and the Petrolona skull which sits on the morphological boundary between Homo erectus and archaic Homo saniens. The review article on fossil man by Cronin et al. 5 and also recent work on planktonic organisms by Prothero and Lazarus⁶ have dealt with this matter effectively. The museum has now, in 1981, removed the labels which previously stated categorically that the Homo erectus people were not our direct ancestors.

It is a fact that the dinosaurs are used to illustrate the principles of cladistics and not their natural history. Similarly, the evolution of man is being used as a vehicle for cladistics, even though this has involved crudely distorting the evidence. It is worth recalling the words that Andrew Huxley used in his Presidential Address to the British Association in 1977.

"Scientists whose findings contradict fashionable social theories are accused of distorting their results through political prejudice and it is suggested that on sensitive topics we should base our beliefs not on what is actually found to be the case, but on the supposed consequences of holding particular beliefs — in effect

that we ought to replace science by wishful thinking. I regard any such attempt to deflect scientific conclusions for political or social motives, however well-meaning, as a betrayal of science.

The situation at the British Museum (Natural History) is suspiciously comparable to that against which Huxley's criticisms were directed.

It was, however, something even more astonishing than all this that stung me, a palaeontologist and evolutionist, into activity⁷. This was the assurance given in writing in 1978 by the Head of the Public Services Department to the creationists 8 that the museum in its new exhibition on evolution (to be opened in 1981) would make it quite clear that the theory of evolution was not a scientific theory. It transpired that this attitude stemmed from the writings of Sir Karl Popper. The museum was now concerned with "concepts of science" as adumbrated by Popper, and the articles of Platnick and Gaffney⁹ and even more recently Tassy¹⁰ emphasized the scientific (in the sense of Popper) nature of cladistics. In marked contrast, palaeontology, the historical side of evolution, was dismissed because it comprised unique events which were by definition unrepeatable and so not subject to test and hence not part of science. This is the view of Patterson 11 which he claimed comes from Popper.

The notion that the process of evolution by natural selection is non-science was based on the idea that "survival of the fittest" is a tautology and hence unfalsifiable. On this point Popper 12 wrote:

"The fact that the theory of natural selection is difficult to test has led some people, anti-Darwinists, to claim that it is a tautology . . Since the explanatory power of a tautology is obviously zero, something must be wrong

"I mention this problem because I too belong among the culprits.... I have changed my mind about the testability and the logical status of the theory of natural selection; and I am glad to have an opportunity to make a recantation.

Ruse 13 and Flew 14 have also dealt with this. (The museum, although initially keeping faith with the creationists, has since withdrawn the film loop concerned, following the adverse review of the exhibition by Barry Cox 15 (see also Miles 16).

Popper 17, following my attack 7 on the ideas

being peddled in his name, has emphatically dissociated himself from his self-proclaimed disciples in the following terms:

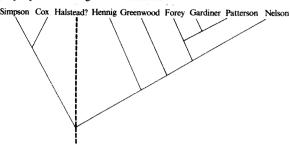

"It does appear that some people think that I denied scientific character to the historical sciences, such as palaeontology, or the history of the evolution of life on Earth. This is a mistake, and I here wish to affirm that these and other historical sciences have in my opinion scientific character; their hypotheses can in many cases be tested. It appears as if some people would think that the historical sciences are untestable because they describe unique events. However, the description of unique events can very often be tested by deriving from them testable predictions or retrodictions.

With the philosophical aspect in better perspective, it became possible to consider what might lie behind the attitudes to evolution and palaeontology being unveiled by the museum's Public Services Department. My suggestions on this stimulated a certain degree of controversy.

Sir Andrew Huxley in his opening of the museum's new exhibit "Origin of Species" stated that he had "been quite unable to comprehend the suggestion that cladism is

How to classify the cladists

Sir - May I propose a cladogram of cladists?

The cladogram is, of course, based only on derived characters appearing late in ontogeny; it makes no claims as to ancestry. (Apologies to Halstead, but he does display a confusing array of derived traits.) London, UK **BRIAN LEITH**

somehow antagonistic to evolution, or that cladism is linked to the theory that evolution progresses by fits and starts, or that cladism is more Marxist than other styles of classification"

That Hennigian or classical cladistics is antagonistic to the gradualist type of evolution is surely evidenced by Rosen, Nelson and Patterson 18:

"Hennig established a criterion of demarcation between sciences and metaphysics at a time when neo-Darwinism had attained a sort of metaphysical pinnacle by imposing a burden of subjectivity and tautology on nature's observable hierarchy. Encumbered with vague and slippery ideas about adaptation, fitness, biological species and natural selection, neo-Darwinism (summed up in the "evolutionary" systematics of Mayr and Simpson) not only lacked a definable investigatory method, but came to depend, both for evolutionary interpretation and classification, on consensus or authority.'

This sounds antagonistic to me.

The latest brand of cladism, the transformed variety, has undoubtedly slid into what seems to me to be an overtly anti-evolutionist stand. Patterson 19 writes:

'Hennig's 1966 book, as the title Phylogenetic Systematics suggests, was based in evolutionary theory. But as the theory of cladistics has developed, it has been realised that more and more of the evolutionary framework is inessential and may be dropped. Platnick (1980) refers to the new theory as 'transformed cladistics' and the transformation is away from dependence on evolutionary theory. In my view, the most important outcome of cladistics is that a simple, even naive method of discovering the group of systematics - what used to be called, the natural system - has led some of us to realise that much of today's explanation of nature, in terms of neo-Darwinism, or the synthetic theory, may be empty rhetoric. Eldredge and Cracraft (1980) provide a detailed criticism of the transformational approach in biology, and the ensuing interest in storytelling about adaptive change.

The link between cladistics and the theory that evolution progresses by fits and starts

(punctuated equilibria) is emphasized in particular by Cracraft²⁰ and is certainly the type of association that a normal reader would obtain from reading Eldredge and Cracraft's Phylogenetic Patterns and the Evolutionary Process²¹

The concept of punctuated equilibria is undoubtedly linked to Marxism, according to Gould²², who claims to be a Marxist. Gould²² sees "notions of gradualism arising largely out of a pervasive political bias [and] . . . the replacing of gradualism with the flip-like style of change which has been appreciated within Marxist philosophy for a long time.'

The current drive against the concept of gradualism is motivated primarily by Marxists this does not mean that there are not plenty of non-Marxists who agree nor does it mean that the views may not turn out to be true. What is objectionable is the distortion of scientific data for ideological purposes.

Finally, I am not opposed to either a cladistic or a Marxist approach being presented. My objection is to the attempt to impose highly controversial concepts on to the general public not by argument or discussion but simply by unsubstantiated assertion. Whalley and Gibbon²³ have pointed out that the current policies being pursued by the museum are diametrically opposed to the 1972 paper to the trustees, on which they are supposedly based, where it was emphasized that the new exhibition scheme "should point out areas of doubt and speculation"

Whatever view is taken of my linking hypothesis, this does not in any way affect the factual account of what has been happening in the museum. It is to be hoped that the minor changes made in the past few weeks herald a new awareness by the trustees of their responsibility towards maintaining integrity in the natural sciences.

NEWS AND VIEWS

Thalassaemia: from theory to practice

from Bob Williamson

THE international symposium on recent advances in thalassaemia, held in Sardinia from June 7th to 11th, was divided quite sharply into two parts. Several molecular biologists presented the latest data on the gene defects causing the various types of thalassaemia found throughout the world, following which doctors from the countries where the disease is common exchanged experiences on the use of this knowledge in programmes for population screening and antenatal diagnosis. The meeting was the first in three years to involve most of the molecular biologists and all of the leading figures involved in control of haemoglobinopathies, and allowed some interesting conclusions to be drawn.

Since the first demonstration that most cases of a-thalassaemia (with depressed a-globin synthesis) are due to gene deletion, the exact gene defects in each of the haemoglobinopathies have been analysed one after another. As the thalassaemias, and in particular β -thalassaemia (in which the synthesis of the β -globin chain synthesis is impaired), protect carriers against malaria, it is not surprising that many independent mutations have spread in populations in malarial areas. One interesting possibility put forward by Herman Lehmann (University of Cambridge) is that a-thalassaemia might not really protect against malaria at all, but rather mitigates the effects of β-thalassaemia (or sickle cell disease) and so is often found in association with it.

Genetic engineering techniques have now allowed a complete understanding of the causes of the major forms of β -thalassaemia in Italy, Greece and Cyprus. In β° -thalassaemia, A. Bank (Columbia University) showed that a point mutation has occurred in many patients at the 5' intron-exon junction of the large intron so that splicing of the nuclear RNA transcript cannot take place at all. Patients homozygous for this point mutation cannot make messenger RNA, and therefore make no β -globin. Fortunately, the splice junction is also a restriction site for the enzyme HphI, and therefore a direct gene analysis (of the patients, or antenatally) should be relatively simple.

In the case of β^+ -thalassaemia, the form most common in Cyprus (and therefore in London), B. Forget (Yale University) reported results from his laboratory and from that of R. Williamson (St Mary's, London) which show that the mutation is within the small intron and creates a new splice site which can act as a preferred alternative to the correct one. This explains why patients are still able to make a small amount of β -globin. Yet another type of mutation, causing premature termination of the β -globin protein chain, has been identified by Y.W. Kan (University of California, San Francisco). It is now clear that the majority of β -thalassaemia cases, as well as those of α -thalassaemia, are a result of either a single point mutation or a gene deletion of one of the globin structural genes. Therefore, hopes that control mutations would be common among the thalassaemias do not appear to be fulfilled. Even cases of 'hereditary persistance of fetal haemoglobin', reported by D. Weatherall (University of Oxford) and S. Ottolenghi (University of Milan), show linkage to the β -globin gene, and therefore are probably caused by a similar type of mutation.

The one new application of molecular biology to antenatal diagnosis was reported by Y.W. Kan (and originated from John Wilson, University of Georgia). He noted that the point mutation causing sickle cell disease, in the codon specifying amino acid 6 of the β -globin chain, eliminates a restriction enzyme site for Ddel. Wilson has used this in a direct analysis of DNA from patients and from the amniotic fluid of a fetus at risk. Previous DNA antenatal diagnoses have depended upon linkage between a restriction site polymorphism and the gene defect, and therefore have required a family study (Kan and Dozy Proc. natn. Acad. Sci. U.S.A. 75; 5631, 1978; Little et al. Nature 285; 114, 1980). If the defect itself can be examined directly at the nucleotide level, it simplifies matters

Bob Williamson is Professor of Biochemistry at St Mary's Hospital Medical School, University of London.

enormously for the specialist in molecular medicine, as both the theoretical problems of gene cross-over and the practical difficulties involved in family studies and the establishment of paternity all vanish.

Perhaps the most interesting view of the meeting concerned the attempts of clinicians in Italy and Greece to implement community programmes to control the disease. Pride of place must surely go to A. Cao (University of Cagliari), the organiser of the meeting, whose efforts in southern Sardinia have cut the incidence of thalassaemia from 1 in 250 live births to 1 in 800. This dramatic threefold reduction is not due exclusively to prenatal diagnosis, but it was very illuminating to learn that even in Sardinia, as a result of intensive popular education programmes, termination of pregnancy where prenatal diagnosis shows the fetus to be affected by this very severe disease is accepted in 95 per cent of cases. This surely indicates that community attitudes to very serious diseases are changing even where one might think that religious attitudes would prevent a successful programme.

D. Loukopoulos (University of Athens) is attempting a similar programme in Greece, but the fact that the country (and the problem) is so much bigger, and the absence of a unified health service and education programme, have meant that his programme has had less impact. However, he is now carrying out over 500 antenatal diagnoses a year, and in some regions in Greece the incidence of the disease is falling. He commented that the fact that affected children are now recieving blood transfusions (up to 20 a year) and very expensive support therapy to remove the iron from their bodies means that there is enormous financial and clinical burden on Greek paediatric departments which did not exist when most children died in the first two years of life. Therefore, the very fact that clinical care has improved (although still quite stressful for the patients) has created a dramatic need for better antenatal diagnosis.

B. Modell (University College Hospital, London) then reported upon the reaction from the Cypriot community in London to the availability of antenatal diagnosis. There has not been a single case of β -thalassaemia within the Cypriot community during the past two years, as a result of intensive community education programmes and the awareness of both the community itself and those general practitioners in North London who serve it.

Parents who were at risk of having an affected child had virtually stopped reproducing before antenatal diagnosis, but now are having a normal number of children, as it can be guaranteed that all of these will be healthy. In this way, it has been shown that far from resulting in a decrease in the number of normal children

being born, antenatal diagnosis with abortion of affected pregnancies has resulted in a large increase in normal children, which is what both the families at risk and the community wish.

However, antenatal diagnosis (whether using fetal blood or DNA) can only deal with the situation in advanced countries at the moment, and even in Britain, Italy and Greece there are still seriously ill children with thalassaemia. Bone marrow transplantation for blood diseases such as the leukaemias is now an established, if risky, clinical practice in several centres, and D. Thomas (University of Seattle) discussed whether this procedure might also work for thalassaemia. The best results in bone

marrow transplantation are achieved with HLA-compatible brothers or sisters, and these certainly exist in thalassaemic families. However, transplantation should be carried out early, when the child is well, and not when the tissues have already been damaged by high levels of transfusion and the iron deposits this leads to. The question facing clinicians in the immediate future is whether to risk the life of a relatively well child with thalassaemia by giving a marrow transplant, knowing that if it works (a 75 per cent chance) the child will be healthy permanently — or to hope for other, less heroic treatment to be developed, knowing that if you guess wrong, the child may die in late teens of a very unpleasant disease.

Minor body mass determination

from David W. Hughes

SPACECRAFT missions to both asteroids and comets have been much in the news recently. One of the aims of these investigations will be the accurate determination of the masses of minor bodies in the Solar System.

From theoretical considerations, the mass of a typical short-period comet has been estimated to be about 1016g. It seems that the direct determination of a comet's mass by observing the perturbation that it induces in the orbit of another celestial body is quite out of the question. One of the closest approaches to Earth of any recorded comet was that of periodic comet Lexell, which on 1 July 1770 came to within 2.25×10^6 km, about six times further away than the Moon. Laplace recorded in his Traité De Mécanique Céleste (Paris, 1805) that this close encounter had no measurable effect on the length of the sidereal year and thus the mass of this comet must be less than 2×10^{-4} the mass of the Earth (which is 6×10^{27} g).

Asteroids are generally bigger than comets and therefore the problem is slightly easier. A great many positional observations are available over a long time period for the largest two, Ceres and Pallas, beginning with the years of discovery, 1801 and 1802. These observations provide information about the accumulated gravitational effects which each of the two bodies have produced in the orbital motions of the other. The total effects are small. Schubart (Astr. Astrophys. 30; 289, 1974) integrated the data for 1802-1970 and found the mass of Ceres to be $(1.17 \pm 0.06) \times 10^{24}$ g. Pallas was smaller — $(2.6 \pm 0.8) \times 10^{23} g$ — and so the error in its mass determination was relatively larger.

A more recent determination of the mass of a minor body has been attempted by analysing the radio-tracking data of a spacecraft as it flies close to the body. The Viking Orbiter 1 made several flybies to within 80-300 km of the Mars satellite Phobos. Radiometric tracking from Earth measured the spacecraft – Earth distance and the geocentric velocity of the spacecraft. The latter was achieved by recording the Doppler shift in the S and X band frequencies transmitted by the spacecraft. Analysis of the gravitational perturbations induced in the orbit of the spacecraft led to a mass determination of $(9.9 \pm 0.6) \times 10^{18}$ g for Phobos — an object which is about 21.5 km across.

The problem of measuring the mass of a comet by using the tracking data of an in situ spacecraft has been analysed by D.K. Yeomans, M. Ananda, W.L. Sjogren and L.J. Wood of the Jet Propulsion Laboratory, Pasadena (see J. astronaut. Sci. 29; 19, 1981). In a representative experiment, the authors decide to determine the mass of the short-period comet Tempel 2 during a rendezvous mission. A solar electron propulsion system (SEPS) has been used to transfer the spacecraft to the comet and the data are collected near perihelion when the comet becomes active. A single slow flyby on the sunward side of the cometary nucleus is assumed.

The main relative spacecraft—comet acceleration is due to the gravitational attraction between the two bodies. There are, however, four additional accelerations to be considered. Comets near perihelion give off a lot of gas and dust, at a rate that varies with heliocentric distance and is probably uneven, the material coming from a series of relatively short-lived active regions on the spinning cometary nucleus. The magnitude of the acceleration effect can thus vary stochastically about some mean value. It also depends on the orientation of the solar array panels, obviously

David W. Hughes is in the Department of Physics, University of Sheffield.

being larger when these are face-on to the flux as opposed to being 'feathered'. Solar radiation pressure also influences the spacecraft and again the effect depends on the area of the spacecraft presented to the radiation flux. Radiation pressure is generally larger than the gas and dust drag but is more easily accounted for as it can be considered constant over short time periods. There is also a tidal acceleration due to the unequal distance between the spacecraft, the comet and the Sun. Finally, spurious accelerations would be present, generated by the spacecraft due to the incomplete shut down of SEPS engines, altitude and articulation control subsystem gas jets. The operation of tape recorders and resonant vibrations of large solar panels also cause problems.

Two primary measurements are taken. Doppler tracking using the Deep Space Network of tracking stations enables the velocity to be found to an accuracy of 0.1 cm s⁻¹ over a count time of 1 min. Spacecraft—comet ranging using, for example, X band (10 GHz), a pulse length of 2 μ s and a pulse repetition frequency of 250 Hz can give an accuracy of 20 – 30 m when the spacecraft is within 1,000 km of the cometary nucleus.

Yeomans and colleagues find that the Doppler tracking data are more useful than the spacecraft-comet ranging data when it comes to determining the mass of the comet. Accuracy is improved by having both. The sensitivity of the mass determination to the stochastic nature of the gas and dust emission indicates that an accurate on-board accelerometer would also improve the accuracy.

Returning to Tempel 2, if the rendezvous spacecraft flies by the comet at a minimum distance of 100 km at a velocity of 2 m s⁻¹ and data are collected for about 8 days from both a Doppler and a ranging system, a conservative estimate is that the mass can be measured to just better than 15%.

Leeuwenhoek's specimens discovered after 307 years

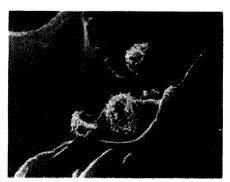

from Brian J. Ford

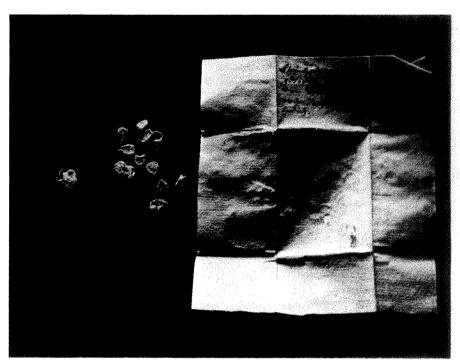

AFTER not being seen since 1674, original specimens sent by the "father of the microscope", Antony van Leeuwenhoek, have been found to be still in existence. A systematic search through the four large files of his letters sent to the Royal Society, revealed nine little envelopes containing original material and fixed to the final pages of three of the letters. Only minute traces of one of the specimens ("tWitte van een schrijff-penne" — white from a writing-pen [quill]) remained, but the remainder were intact. The sectioned material was compressed into compact masses, but otherwise the specimens were in excellent condition.

Antony van Leeuwenhoek (1632-1723) lived and worked in Delft where he produced his own single-lens microscopes. His status as the founder of microscopy derives from decades of dedicated and accurate observation, faithfully recorded in lengthy letters most of which were sent to London. His observations of spermatozoa, bacteria and a host of histological specimens were without precedent. Many workers have since commented on the 'crudity' of his techniques, emphasizing that his material was examined whole, or 'torn apart', and it has become generally accepted that section-cutting did not begin until the middle years of the nineteenth century.

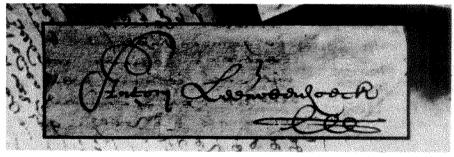

The discovery of his specimens reveals two examples of plant material cut as fine sections. They are "Pit van vlier" — elder pith, and "Kurk" — cork. The conclusions that can be drawn from these specimens about seventeenth-century microtechnique are many (a fuller account by the author appears in the current *Notes and Records of the Royal Society*) but the central finding is that van Leeuwenhoek, working at the dawn of microscopy, could prepare by hand sections that would be acceptable for laboratory use today.

Brian J. Ford is in the Science Unit, Cardiff.

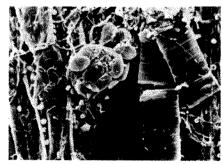

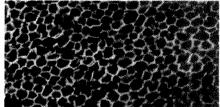

"Stuckjens vande gesicht senuwe van een koebeest over dwars afgesneden" — pieces of optic nerve of a cow cut in transverse section. The specimens were attached to a letter dated 1 June 1674, and signed by van Leeuwenhoek, as shown below.

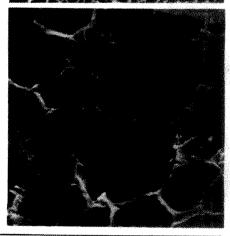

Right, the stereoscan microscope reveals the regular, fine cut of the sections of cork. Though the hand-cutting technique seems primitive, the results are good enough for present-day microscopy. Below right, the sections of cork shown reveal the room-like appearance from which the term 'cell' was derived in 1663.

Left, high-magnification examination of the cell walls reveals occasional fungus spores. Thread-like hyphae occur from time to time in the sections, but have caused no structural change over 307 years. Right, specimens of papery material which van Leeuwenhoek claims arose from water are attached to a letter dated 17 October 1687. Algal cells and diatom chains revealed in this scanning electron micrograph confirm his finding.

Mixed-species foraging groups

from Jared M. Diamond

A bird-watcher is walking through a tropical rainforest, dejected at having seen and heard almost no birds for the last hour. Then a faint sound becomes audible afar, gradually grows louder and approaches. Soon the forest comes alive with dozens of bird species busily foraging together and calling simultaneously. The feverish excitement lasts for a few minutes, dies down as the flock moves on, and the forest is again silent and seemingly devoid of birds. A mixed-species foraging party has passed.

Analogous scenes repeat themselves daily on all the continents and in all the oceans, in the treetops, on the ground and underwater. The most familiar mixed foraging parties involve birds; the most spectacular ones, African open-country grazing mammals. Further examples are being discovered among fish, cetaceans and primates, and in at least six cases birds and primates have been found regularly associated with each other. The growing literature on mixed foraging parties (flocks, herds, or schools) has focused on four main questions. Are flocks chance aggregations or always composed of the same individuals? Who leads, and who follows? Why do different species associate? Why do the species sometimes resemble each other in appearance and call far more closely than one would expect from their taxonomic relationship?

Recent papers on mixed bird flocks of the neotropics1-4 have revealed how unexpectedly initimately the lives of flock members belonging to different bird species are intertwined. These authors introduced to the study of mixed flocks techniques for recognizing individual birds by capturing, colour-banding and releasing them. Using these methods they found that the core of a flock consists of individuals of different species that forage together daily for many years, probably for their whole adult lives. Up to a dozen core species are each represented by one pair or family, whose territorial boundaries coincide among the core species and which may roost at night in the same tree. Even territorial confrontations are shared: when one flock happens to meet the neighbouring flock at the territory boundary, the Bluish-slate Antshrikes, Dusky-throated Antshrikes, Dot-winged Antwrens and White-flanked Antwrens of one flock simultaneously display and call to their conspecifics in the other flock. Individuals of additional flock species with smaller territories than the core members join the flock only when it enters their territory. Species with larger territories than the core members forage first with one flock, then with a neighbouring one a few hours later. Some species switch between

two distinct types of flock that occur in the same area: a slowly moving flock in the understory basically consisting of insectivorous antbirds, and a rapidly moving flock in the canopy of omnivorous tanagers and honeycreepers.

Are some species leaders and others followers? Usually there is a leader species (the 'nuclear species'), which is conspicuous in its plumage, frequent vocalizations and nervous behaviour such as wing- or tail-flicking, and which forages in groups of several individuals⁵. Nuclear species of bird flocks are often tits in Europe, North America and west Africa. babblers in tropical Asia, thornbills and fairy-wrens in Australia, gerygone warblers in New Guinea, and antbirds and tanagers in the neotropics (see, for example, ref. 6). Other species follow the conspicuous noisy whirlwind of the nuclear species group. In most bird-mammal associations, the mammal is the leader, the bird the follower, but tamaring monkeys of the neotropics are thought to follow tyrannid flycatchers.

Flocking seems to serve several purposes simultaneously, and different motives may predominate in different cases. Some of the leading theories are the convoy theory, gang theory, beater theory, pirate theory and feeding efficiency theory.

Convoy theory. Flocks may be an antipredator device, like the World War ship convoys that were so effective against U-boats^{7,8}. The more individuals in a flock, the more eyes and ears there are to detect a predator, the lower is the chance of a given individual being the victim of an attack, the harder it is for the predator to focus on any target amidst all the activity and the better is the flock able to mob or ward off the predator. Observations that support the convoy theory include that lone birds peer about more, and spend less time feeding, than birds in a flock9. On African plains, near-sighted zebras with acute hearing associate with far-sighted species such as ostriches, wildebeest and giraffes, so that each complements the other's detector capabilities. Near-sighted gleaning birds tolerate the proximity of far-sighted salliers that occasionally rob them of food (antwrens tolerating antshrikes in the neotropics, tits tolerating drongos in Africa): the improved predator detection is worth the lost food.

Gang theory. Flocking may permit flock members access to resources within a territory whose owner would be able to expel the members if they were solitary. Thus a flock is like a gang of marauders overwhelming a victim by their numbers.

Jared M. Diamond is Professor of Physiology at University of California Medical School, Los Angeles. For example, on Caribbean reefs the Three-spot Damselfish can inhibit single Stripe Parrotfish from feeding in its territory, but not parrotfish schools¹⁰. Similar cases are reported for Australian honeyeaters, Australian corvids and North American mockingbirds^{11,12}.

Beater theory. Tiger hunters follow a line of beaters who create a disturbance and flush out tigers. Similarly, some flock members, in the course of their own foraging, flush prey that a different species can capture. For example, gleaning and bark-feeding birds disturb resting insects into flight, where a sallying bird may catch them. Drongos, which are sallying insectivores, are notorious for following large or active animals so that they can catch insects disturbed by these beaters. Beaters used by drongos include elephants, giraffes, buffalo, ostrich, baboons and occasionally humans in Africa; monkeys in Borneo and Celebes; and babblers in New Guinea. In the neotropics, monkeys are used as beaters by the hawk Harpagus bidentatus. Africa's Ground Hornbills follow baboons that are turning over logs. African arboreal monkeys that eat fruit husks are joined by squirrels that eat the fruit kernels, ungulates that eat the fruit falling to the ground and hornbills catching insects flushed out by the monkeys.

Pirate theory. From using other species as beaters to flush out food that the beaters could not take, it is a small step to the role of pirate: seizing food that another flock member has caught. Drongos practice occasional piracy on other birds in New Guinea and African flocks¹³; antshrikes victimize antwrens in neotropical flocks. Why does the victim tolerate the pirate? Probably because the pirate is a noisy, farsighted sallier that detects and warns of predators.

Feeding efficiency theory. Species that flock together have similar diets, although they differ in foraging technique, height and substrate9,14,15. At first it seems in defiance of competition theory that species with similar diets should flock, and that flocking should vary inversely with food density 16,17. Yet flocking promotes feeding efficiency in several ways. The more individuals searching, the more likely is a good feeding patch to be found. Animals can learn new foraging techniques from allospecifics18: Morse saw a Blue Tit fly up to a Lesser Spotted Woodpecker pecking at bark and begin pecking next to it. Perhaps more important, by travelling together. species with similar diets can keep track of where food has already been gathered and is no longer worth seeking¹⁷. Imagine five janitors who clean a large hall and are paid per kilogramme of trash collected. One janitor uses his hands, one a pitchfork, one

a broom, one a vacuum-cleaner and one a carpet-sweeper. Each janitor is better adapted than the others to collecting certain trash items, but there are many items that can be collected by any of several janitors. A good strategy for all janitors is to forage together, thereby constantly assuring themselves of trash-rich areas and avoiding areas partly cleared by other janitors.

For whatever reason species do forage together, it is striking that flock members of widely different families often resemble each other in appearance, vocalizations, or both. As examples of this co-evolutionary phenomenon, termed social mimicry, Moynihan¹⁹ noted that flocking tanagers in the mountains of Panama are mainly black and/or vellow, in the northern Andes brilliant blue or blue and yellow, and in the south-central Andes blue-grey dorsally and brown ventrally. A prime example of this tendency for birds of a feather to flock together is the 'brown and black flock' of New Guinea, first noticed by the flamboyant Italian explorer Count Luigi d'Albertis in 1880 and rediscovered much later by Bell²⁰. The flock involves up to 22 medium-sized, omnivorous bird species from seven families (birds of paradise, babblers, whistlers, drongos, cuckooshrikes, honey-eaters and flycatchers). All these species are either mainly rufous or mainly black; in three, the male is black, the female rufuous. The flock is led by a group of the babbler Garritornis isidori, of which one individual is the actual leader and has a distincitive 'leader' call while his/her conspecifics have a 'follower' call. At least five other species in the flock mimic one or other of the babblers' calls.

Why should species from such different families converge in plumage? We are not dealing here with detailed mimicry of plumage patterns, but merely broad resemblances in overall colour. Moynihan points out that interspecific signals are required so that mixed flocks can form and maintain cohesion. The convergence in these signals may be for economy: it is much easier for a flock member to stay with the flock and avoid wandering off with some non-flock species if it need only remember to look for brown or black birds, instead of keeping 21 different colour patterns in mind.

THE CHEMISTRY OF THE SUN

Although in the year 1866 a great many people were familiar with the spots on the sun, those who had been favoured by a sight of a total eclipse, and many more who had read the accounts of total eclipses, knew that there was a great deal more of the sun than one generally sees. From the time of Stannyan, who observed the prominences at Berne, down to the year 1842, let us say, several eclipses had been observed. and very beautiful coloured phenomena had been recorded by different observes. Red things had been seen projecting round the dark moon during the time of eclipse, and although many held them to be beautiful effects produced by the passage of the moon over the sun, or even clouds in the atmosphere of the moon coloured by the strange way in which the solar light then fell upon them, a larger number of people, on the other hand, insisted that these things must really belong to the sun. Now if that were so, it was perfecly clear that we should not be contented with merely observing the chemical nature of the spots.

We have a round dark moon, which in this case is represented as entirely covering the sun; then these different prominences and luminosities, this wonderful set of streamers, or whatever you like to call them, which seem to veil, or to render less distinct, something else which is lying beyond them. You will see here that some of these prominences are red, and others have a yellow tinge, and that, quite independent of the colour of the prominences, we have the most exquisite coloured effects. Sometimes the radial structure is not so marked, and reveals

Eclipse of 1870. Photograph of the corona taken at

indications of structure further away from the sun. You see wonderfully delicate tracery, lines being seen now in one part and now in another. In the photograph taken during the eclipse of 1870 we see that the luminosity of the solar atmosphere was excessively irregular, by which I mean that in one part we get a very considerable excess of light, quite independent of the sharply defined prominences. whereas in other portions the atmosphere of the sun at the same height is not nearly so luminous. Now in none of these cases have we been able to see the thing which struck us most clearly the moment the artificial eclipse system was set at work. It is a good indication of the extreme difficulty of making observations during eclipses, and how important it is that one should have a method which makes us independent of

From Nature 24, 21 July, 271, 1881.

Origin of the galaxies

from Joseph Silk

COSMOLOGISTS generally believe that galaxies formed as a consequence of the growth of tiny density fluctuations in the very early Universe. The remarkable uniformity of the cosmic microwave background radiation has provided convincing evidence for the high degree of regularity of the Universe at an early epoch but within the past year two groups of astronomers, at Florence and Princeton, have reported evidence for a very weak anisotropy on an angular scale of 90°, which is probably produced by similar matter fluctuations to those from which the galaxies evolved.

One of the most tantalizing issues in cosmology concerns the origin of these fluctuations. It is thought that the initial conditions of the big bang might provide an answer. Perhaps the Universe is the way it is because of the way it was. Surely the resourceful cosmologist can improve on this hollow echo of creationism, for if the initial conditions were very different, then we would not be here to take stock of the situation. This concept of the observer's role in determining the state of the Universe has been elevated by Robert Dicke and Brandon Carter to the status of a fundamental cosmological principle: the anthropic principle. Its power arises

Joseph Silk is in the Astronomy Department at University of California, Berkeley

because the growth of fluctuations is inevitable from the beginning of time.

Consider the history of a fluctuation destined eventually to form a galaxy. It grew in amplitude throughout much of the early expansion of the Universe. The earliest epoch that the cosmologist can usefully discuss is the Planck instant, a mere 10-43 second after the singularity. At this time, our galaxy-sized fluctuation must have had an infinitesimal but nonzero density contrast. These inhomogeneities are best considered as fluctuations in the spatial curvature, or slight wrinkles in the geometry of space-time. The magnitude of such primordial wrinkles must be about 1 part in 103, if fluctuations in the energy density are considered; for fluctuations in the matter component alone, the associated wrinkles attain a considerably smaller but well defined value. Were the fluctuation amplitudes much smaller, galaxies would not have formed by now; were they much larger, eventual collapse in the early Universe would have formed separate topologically disjoint universes, bearing little relation to our observed universe.

Although this argument purports to show that the initial conditions may have been unique, it certainly does not provide any explanation. One is left with the following conundrum. The very early

Universe was uniform to a high degree. However to form galaxies, fluctuations must have been present at an exceedingly small but non-zero level. This situation is aesthetically unappealing - granted that the early Universe must have been very nearly uniform, one would obviously prefer to begin with a perfectly homogeneous and isotropic expansion, and fluctuations see develop spontaneously at some later epoch. No one has been able to discover a means of generating fluctuations over a sufficiently large scale to form galaxies in the standard big bang cosmology. To some cosmologists, this failure has provided sufficient reason to reject the standard model. Some have opted for an initially cold big bang in the hope that cold matter may be more susceptible to fragmentation. Others have taken a stronger stance, and rejected the big bang entirely.

A fascinating resolution of this cosmological dilemma has been recently proposed by Ya. B. Zel'dovich of the Space Research Institute, Moscow (Mon. Not. R. astr. Soc. 192; 663, 1980) and Alexander Vilenkin of Tufts University (Phys. Rev. Lett. 46; 1169, 1981). Recent applications of elementary particle theory to the very early Universe imply the possibility of a novel mechanism for the spontaneous generation of the seed fluctuations from which galaxies eventually formed. The origin and nature of elementary particles can be understood in terms of a class of theories known as the grand unified theories (GUTs), which seek to unify the electromagnetic, weak and strong nuclear forces into a single theoretical framework. Above the grand unification energy of about 1015 GeV, these fundamental forces of nature all play an equal part, and matter is completely symmetrical in all its properties. The very early Universe provides a natural laboratory for testing GUTs, since particle energies attained then greatly exceed those produced in any manmade particle accelerator. One of the most elegant consequences of GUTs is that they predict (at least in order of magnitude) the observed baryon asymmetry of the Universe. The breakdown of symmetry occurs some 10-35 second after the big bang, when particle energies have dropped below the grand unification energy. This produces a slight excess of particles over antiparticles which is crucial to the existence of an environment in which life could evolve, for the fact that we and our surroundings consist exclusively of matter rather than antimatter implies that in the very early Universe, when the cosmic blackbody radiation copiously produced particle-antiparticle pairs, the amount of matter exceeded that of antimatter by about 1 part in 109. Our very existence is therefore a consequence of GUTs and the breakdown of symmetries as the Universe expanded and cooled, for a Universe which precisely conserved matter-antimatter symmetry would have undergone considerable annihilation; little residual matter (or antimatter) would remain.

· 医环状结合 - 医皮肤结合 - 10 - 10 kg - 10 - 10 kg m - 10 kg

Zel'dovich and Vilenkin argue that GUTs may have profound implications for the large-scale structure of the Universe. The breakdown of symmetry at 10-35 second can be regarded as a phase transition. A useful analogy is an isotropic ferromagnet, which when cooled below a critical temperature (the Curie point) spontaneously develops magnetism. The direction of magnetization is indeterminate and random, and may vary in different regions or domains. The GUTs phase transition may involve the spontaneous generation of a domain structure. The symmetry breakdown is believed to be effected via an intermediary class of particle - the Higgs particle - and its associated fields. These are important in the unification of strong and electroweak interactions, being responsible for the masses of the elementary particles once the symmetrical state is broken. As the Universe cools, the symmetry breakdown occurs because particles and radiation are no longer energetic enough to create the full panoply of states of all types of particle predicted by GUTs. The end state of the matter is characterized by a vacuum state of lowest energy. In the classical physics regime, the vacuum has approximately zero energy, although small fluctuations are present. The fluctuations are variations in the energy of a reservoir of virtual pairs of particles and antiparticles that are released under extreme conditions of temperature or gravitational stress. The vacuum state after the GUTs phase transition has a finite energy density associated with the Higgs field. It is believed that the Universe began with a very large vacuum energy density of almost equal magnitude but opposite sign, forming a false vacuum state, so that one ends up after the phase transition in the true vacuum of zero energy.

In fact, the true vacuum state is not unique. Although the minimum energy state of the Higgs field has a universal value, implying the same energy density everywhere, the direction of the associated field is indeterminate. Multiple true vacuum states are possible, depending on the degree of complexity of the Higgs field. The phase transition can result in the formation of different domains of vacua, corresponding to the multiple vacuum states. The direction but not the magnitude of the Higgs vacuum expectation value differs in each domain. The domain boundaries are characterized by gradients in the Higgs field, and therefore contain energy density; they also consist of residual false vacuum that has not undergone the phase transition. When the Higgs particles have decayed, the Universe contains the remnants of these boundaries in the form of topological structures of false vacuum that may contain a very considerable energy density.

Theory indicates that possible forms for

the domain boundaries are topological discontinuities that can be either two-, one-, or zero-dimensional in character. There are two-dimensional walls, one-dimensional strings, or monopoles, which are point-like singularities. An important characteristic of the energy density associated with the monopole's structure is that it effectively behaves as a rest-mass, and assumes a progressively more important gravitational role as the radiation is redshifted away. The walls and strings suffer very little friction from the ambient radiation and matter, and the tendency of these initially highly convoluted structures to straighten out causes them to move at near the speed of light on the horizon scale. Density fluctuations are generated on and below the horizon scale, and larger and larger fluctuations develop as the horizon scale grows.

In fact, expanding walls can be excluded by simple astrophysical considerations. Zel'dovich, Kob'zarev and Okun pointed out (Zh. Eksp. Teor. Fiz. 67; 3, 1974) that such walls should be extremely massive, and would grossly perturb the cosmic microwave background radiation. However strings are quite another matter. Their one-dimensional structure implies that their influence in the present epoch is relatively modest. Strings may still lead to sizable density fluctuations. The process of generating density fluctuations continues after the phase transition at 10⁻³⁵ second, perhaps until the present epoch if the strings can survive. At formation, the strings are very tangled, and both infinitely long strings and closed loops are present. Dissipation tends to reduce the tension in the strings on scales smaller than the horizon, and the strings gradually straighten out. New strings are likely to form as intersecting strings form closed loops; this provides a principal means of straightening the strings. The expansion of the Universe stretches the strings on scales larger than the horizon, and the characteristic dimension of a string at any enoch is in fact the horizon scale.

The density fluctuations generated by the strings can provide the seeds for galaxy formation. The mass of a galaxy is first contained within the horizon at an epoch of about 10 yr and the mass of a galaxy cluster after about 104 yr. Strings will be present on the horizon scale moving at light speed and their gravitational pull will induce density fluctuations. Zel'dovich argues that the density of infinite strings remaining from the GUTs phase transition amounts to about 0.1 per cent of the mean cosmological density. This implies that the expected amplitude of density fluctuations is of the order of 0.1 per cent. Such fluctuations survive the radiation even when their growth is inhibited by the frictional effect of radiative viscosity. After the decoupling epoch, the fluctuations grow in amplitude uninhibited by the radiation, accreting the surrounding matter. Galaxy formation eventually occurs once the fluctuations become of very large amplitude and collapse.

How inevitable is such a scenario? It seems that in general types of GUT, these topological singularities (either walls, strings or monopoles) will form as the symmetry breakdown occurs, depending on the degree of complexity of the Higgs field. The only requirement is that the Higgs field possess a finite correlation length, beyond which its expectation value in different locations is completely uncorrelated. This provides our best hope for understanding galaxy formation in an initially homogeneous and isotropic universe. Galaxies may therefore have originated from a tangle of strings spontaneously produced some 10-35 second after the big bang. The strings are best visualized as topological knots of high energy density that may be either of infinite length or closed loops. As the Universe expands, the strings untangle, continuously generating sizable density fluctuations via their gravitational effects on scales less than the instantaneous horizon scale.

Cosmologists are not entirely convinced by this scheme, since it involves rather specific assumptions about elementary particle theory concerning the nature of the Higgs field that have not received widespread acceptance. One difficulty is that not only strings are produced by the GUTs phase transition. Massive monopoles are

predicted by the simplest GUTs, and these particles could dominate the present mass density of the Universe, contrary to observation, unless the theory of the very early Universe is carefully adjusted. Perhaps strings will only meet universal acceptance if more direct proof of their existence is forthcoming. This is most likely to emerge from their effect on electromagnetic radiation, in the large-scale angular anisotropy of the cosmic microwave background radiation. Another intriguing possibility is that the gravitational lenses, recently identified with close pairs of quasars having strong spectral similarities, may be due to the gravitational deflection of light by cosmological strings.

Bose-Fermi equivalence and soliton theory in solid-state physics

from R. K. Bullough

NONLINEAR oscillators and nonlinear wave mechanisms are providing the key to our understanding of an increasing number of fundamental processes in physics, chemistry and biology. Some years ago nerve axon pulse propagation was modelled by the nonlinear Hodgkin-Huxley or FitzHugh-Nagumo equations. Now nonlinear wave equations are providing insights into, for example, the way chemical concentration waves may implement the changes in anatomical structure demanded by a mutant gene, or cell division in the emerging embryos of sea urchins.

Although most of these nonlinear systems can be handled by the theoretician only by use of large computing machines, there is a large and growing class of nonlinear wave equations which so far have been applied in theoretical physics rather than theoretical biology, and which can be solved analytically, that is, in terms of the familiar mathematical functions. Many of these systems have soliton solutions—the subject of this article.

A word first on nonlinearity; even at school we learn to write down the equation of motion for the angular displacement u of a simple pendulum in the form $Ml d^2u/dt^2 = -Mg \sin u$. Then immediately linearize this equation by replacing $\sin u$ by u and so gain the harmonic oscillator equation d^2u/dt^2 + (g/l)u = 0 which has $\cos(g/l)^{1/2}t$ or $\sin (g/l)^{1/2}t$ as solution. But the linearized theory is applicable only if u is small. So what happens if the pendulum is rigid and can turn right over so that u is 2π or bigger? And what is the situation if we couple such oscillators together in a regular array to form a model crystal? In linear approximation we gain the socalled Klein-Gordon (KG) equation, $u_{xx} - u_{tt} = m^2 u$, which is familiar (the

notation is the convenient one $u_{xx} \equiv \frac{\partial^2 u}{\partial x^2}$, etc. and m here is a number playing the part of a mass). But the nonlinear analogue is the sine-Gordon (s-G) equation $u_{xx} - u_{tt} = m^2 \sin u$ (the name is no accident!). The s-G has soliton solutions but the KG does not.

This word 'soliton' was coined by Norman Zabusky and Martin Kruskal (Phys. Rev. Lett. 15; 240, 1965) who were concerned with a very different-looking wave equation, the Korteweg-de Vries (KdV) equation, $u_t + 6uu_x + u_{xxx} = 0$, and in essence they observed that its solitary $u = \frac{1}{2}V \operatorname{sech}^2 \{\frac{1}{2}V^{1/2}\}$ solution. (x - Vt) asymptotically preserved (or exchanged) both its form and its speed V in collision with other such solitary waves travelling at different speeds. Because of this particle-like property, these solitary waves were dubbed solitons. We now know that this behaviour typifies a whole class of nonlinear wave equations, outstanding examples being the KdV, the modified KdV (MKdV) $v_1 + 6v^2v_x + v_{xxx} =$ 0, the nonlinear Schrödinger equations (NLS) $i\psi_t = \psi_{xx} \pm 2\psi |\psi|^2$ (with ψ complex) and the s-G. Clearly the solutions of such equations could be superb examples of 'elementary excitations' in some context of many-body physics.

With this in mind, solid-state physicists, in particular, have been quick to use solitons to explain the high, anisotropic and essentially one-dimensional, non-ohmic electrical conductivity of certain organic polymers like TTF-TCNQ at temperatures $T \sim 3$ K, or the central peak observed in the neutron-scattering spectrum from crystalline SrTiO₃ in the displacive regime, or the central peak in the spec-

R. K. Bullough is Professor of Mathematical Physics in the Department of Mathematics, The University of Manchester Institute of Science and Technology. trum of the effectively one-dimensional ferromagnetic crystal CsNiF₃ for $T \approx 10$ K, and so on. Already in 1978 the conference report 'Solitons and Condensed Matter Physics' (eds A. R. Bishop and T. Schneider; Springer) was able to review a wide range of such applications.

The physical insight displayed in many of these investigations is admirable. Still it seems a pity that the word soliton is so often misused: sometimes it simply means a solitary wave (a pulsed solution with argument (x - Vt)) or even just a lump; jacobian elliptic functions like cn(x; k) (which tends to $\cos x, k \to 0$, or $\operatorname{sech} x, k \to 1$) are called 'multisolitons' or a soliton 'lattice'. However, there is a mathematical structure surrounding the solitons and their collision properties which does not surround the simpler solitary waves; and this mathematical structure may be relevant to the physical problem in hand.

A case in point is the interesting paper entitled 'Soliton Lattice in Polyacetylene. Spin-Peierls Systems and Two-Dimensional Sine-Gordon Systems' by Baruch Horovitz (Phys. Rev. Lett. 46; 742, 1981)—as well as a frequent misuse of the word soliton in this way in a series of papers by K. Maki and his collaborators who are referenced in the Horovitz paper. In his paper, Horovitz treats three physical systems: a fermion system concerned with the insulator-to-metal transition at ~1% doping observed in polyacetylene, which is explained in terms of a charge carrying soliton 'lattice' or soliton 'droplets' of that lattice; a 'lock-in' phase transition in a boson system engineered by quantum corrections to the classical s-G: and the first-order phase transition observed in the magnetic spin system TTF-BDT (Cu) [tetrathiafulvalene-biscis - (1, 2 - perfluoromethylethylene - 1,,2 dithiolato)-copper] in a strong magnetic field (~120kG) at low temperatures

(~10K). The attraction of the analysis is that all three very different physical problems are shown to be mathematically equivalent. So it is a pity, and I think misleading to the physics, that the author does not make proper use of the mathematical structure surrounding the theory of solitons.

In his first example the author uses Peierls's idea (subsequently extended by Fröhlich as an incipient theory of superconductivity) that the electrons in a onedimensional lattice with a half-filled band can lower their energy if a gap in the electron energy spectrum is induced by a suitable periodic distortion of the ion lattice. If the lattice distortion moves (as a phonon), the ions' charges stay locked to their sites; but if the lattice and its distortion have incommensurate periods, the electrons can travel freely with this phonon and constitute a resistanceless current. In practice this moving 'condensate' is pinned—typically by a periodic potential like $\cos \phi(x, t)$ depending on the condensate phase ϕ . In this particular case the current is carried by the soliton 'kink' 'antikink') solutions, (or $4 \tan^{-1} \left[\pm \exp \left\{ m \left(x - Vt \right) / (1 - V^2)^{1/2} \right\} \right]$ of the s-G. Such a theory describes the nonohmic conductivity of TTF-TCNQ for T < 4.2K quite well (see Cohen et al. Phys. Rev. Lett. 37; 1500, 1976; and Trullinger et al. Phys. Rev. Lett. 40; 206, 1978, and earlier papers). Note that the kink $\phi = 0$ as $x \rightarrow -\infty$, but jumps rapidly from 0 to 2π in a small region of order m^{-1} about (x -Vt); the antikink jumps from 0 to -2π . Horovitz looks for a periodic lattice of kinks and antikinks in which the lattice ion displacement field $\Delta(x)$ swings (on some scaling) between $\pm 2\pi$ about the lattice sites. A sequence of s-G kinks and antikinks might describe just such a situation; however, such a multisoliton solution of the s-G at rest is not stable.

The mathematical problem in all three cases can be reduced to solving a Diractype eigenvalue problem for two-component spinor eigenfunctions $\psi_n(x)$ in the presence of the ion displacement field $\Delta(x)$ such that the total energy $E_0 = \Sigma' \varepsilon_n + \int \mathrm{d} x \, \Delta^2(x)/2 \, n \lambda$ is minimized; the $\Sigma' \varepsilon_n$ is the contribution of the eigenenergies of occupied electron states and λ a coupling constant. The eigenvalue problem takes the form $\hat{L}\psi_n(x) = \varepsilon_n\psi_n(x)$ in which \hat{L} is a Hermitean 2×2 matrix differential operator: $\hat{L} \equiv i\sigma_3 \partial/\partial x + \Delta(x)\sigma_1$ where σ_3 and σ_1 are Pauli matrices.

Experts in soliton theory will immediately recognize this eigenvalue problem as essentially that used by Zakharov and Shabat to solve the NLS in 1972. Likewise it solves the MKdV $v_t - 6v^2v_x + v_{xxx} = 0$. It looks uninteresting for solitons because the eigenvalues must be real (\hat{L} is Hermitean) and we know that solitons are associated with complex eigenvalues. However, the point of all this here is the following: it is known that for the MKdV

(or for the NLS or the s-G for that matter) a 2×2 matrix \hat{B} depending on v, v_x, v_{xx} and the ε_n can be found so that the MKdV equation is equivalent to the operator equation

$$\hat{L}_{t} = [\hat{B}, \hat{L}] \equiv \hat{B}\hat{L} - \hat{L}\hat{B}$$
 (1)

The pair of matrix operators (\hat{B}, \hat{L}) which makes equation (1) the MKdV is the familiar Lax pair for the MKdVnamed after Peter Lax who first found this form for the KdV in 1968. To introduce it here we have extended $\Delta(x)$ by letting it depend on the parameter t and set $\Delta(x, t) \equiv v(x, t)$ so that $\Delta(x, t)$ follows the MKdV 'flow'. It is easily checked that equation (1) is the MKdV flow if, and only if, the ε_n s do not depend on t even though the scattering potential $\Delta(x, t)$ in \hat{L} and the eigenfunctions ψ_n now do so. The MKdV is thus an isospectral flow in this sense. If a nonlinear equation like the MKdV can be put in the form of equation (1), we can expect to solve it for appropriate boundary conditions by the so-called inverse scattering method. This method generalizes the Fourier transform for linear problems to the present class of nonlinear problems via the isospectral transform $\hat{L}\psi_n = \varepsilon_n \psi_n$. If the equation has soliton solutions we can find them through the complex eigenvalues ε_n in this way.

The key point is that the ε_n s remain stationary under the flow. Thus if $\Delta(x+t)$, of single argument x+t, is a particular solution of the MKdV for any t, we might guess that it will minimize the contribution of the electron eigenenergies ε_n to the total energy E_0 for all t; furthermore, we know that under the MKdV flow with appropriate boundary conditions, $\int v^2 dx \equiv \int \Delta^2 dx$ is also a constant of the motion. Thus we guess that $\Delta(x+t)$, or scaling t, $\Delta(x+\gamma t)$ minimizes E_0 for an appropriate choice of γ .

Horovitz took a different route: he converts the spinor eigenvalue problem to a Schrödinger problem with scattering potential $\Delta^2 - \Delta'(x)$ where $\Delta'(x) \equiv \mathrm{d}\Delta/\mathrm{d}x$. He argues, incorrectly in my view, that this is of KG type and uses results in perturbation theory taken about the s-G equation by linearizing this equation about its kink solution to set $\Delta^2(x) - \Delta'(x) = U''(\phi(x))$ and to infer that $U(\phi(x)) \equiv \Delta_1^2(1-\cos(\phi(x)))$. This potential is the s-G potential in its Hamiltonian

$$H = \int \left\{ \frac{1}{2} \phi_{x}^{2} + \frac{1}{2} \phi_{x}^{2} + m^{2} (1 - \cos(\phi(x))) \right\} dx$$
 (2)

so Δ_1 is a mass m (Hamilton's equations for a field $\phi(x,t)$ generate the s-G from equation (2)).

Those familiar with the history of soliton theory will, however, see in the transformation $\Delta^2(x,t) - \Delta(x,t)_x = u(x,t)$ the celebrated Miura transformation which moves a solution $\Delta(x,t)$ of the MKdV to a solution u(x,t) of the KdV $u_t - 6uu_x + u_{xxx} = 0$! It is a curious fact, associated

more with the theory of jacobian elliptic functions than with solitons, that the KdV has the solution $u(x + \Delta_1^2 t) \equiv u(\xi)$ given by $u(\xi) = \Delta_1^2 \cos \phi(\xi)$ providing $\phi'(\xi) =$ $2\Delta_1 \sin \left\{\frac{1}{2}\phi(\xi)\right\}$ so that $\phi'' = \Delta_1^2 \sin \phi$. Certainly this is the equation of motion (in the 'time' variable $\xi = x + \Delta_1^2 t$) of a pendulum capable of large angular displacements; and it has the static kink solutions $\phi = -\pi + 4 \tan^{-1} \exp \Delta_1 \xi$ in which the pendulum turns from upside down very slowly through angle 2π back to upside down. Nonetheless, it derives from a wave equation, the MKdV, very different from the s-G, and the physical associations it conveys are also very different.

Of course, like a good physicist, Horovitz still finds a correct mathematical solution for his lattice which for large period does indeed behave like a series of alternating kinks and antikinks of the s-G. He then finds that this lattice is stable for large doping levels (large values of the phonon-electron coupling constant λ) but becomes unstable for small λ . The formation of droplets of this lattice is suggested to herald the observed insulator-to-metal transition observed in polyacetylene.

In a similar way his so-called bose problem appeals to the fact that if the s-G hamiltonian equation (2) is linearized about a kink and the resulting small oscillations quantized as 'phonons', this quantum correction is essentially the energy of the fermion soliton lattice with a change in sign. Thus there is a first-order phase transition as the coupling constant λ is reduced. Similar considerations apply to his spin problem where $\pm \frac{1}{2}$ spins are carried by the solitons.

The moral of this interesting paper seems to be that good physical insight leads to good physics. But soliton theory is now so important in many areas of nonlinear theoretical physics that a good understanding of it has become an essential technical prerequisite for the practising theoretician. This is particularly true in high-energy physics where mathematical structure may be the only guide. It is a remarkable fact that the so-called spin $-\frac{1}{2}$ xyz lattice model can be mapped exactly, in the continuum limit of zero lattice spacing, onto the massive Thirring model (a relativistically co-variant fermion field theory) and that this maps exactly onto the quantized s-G model (a co-variant boson theory). This formal fermion-boson equivalence, as well as the remarkable mass spectrum of the quantized s-G, has stimulated much work on nonlinear field theories, especially the gauge and supersymmetric gauge theories, in high-energy physics. It has also recently stimulated a quantum version of the inverse scattering method for solving some of these quantized problems exactly. Apparently it was these ideas on fermion-boson equivalence that motivated Horovitz's line of analysis in his interesting paper on solid-state physics.

REVIEW ARTICLE

Actions of cholera toxin and the prevention and treatment of cholera

Jan Holmgren

Institute of Medical Microbiology, University of Göteborg, S-413 46 Göteborg, Sweden

The drastic intestinal secretion of fluid and electrolytes that is characteristic of cholera is the result of reasonably well understood cellular and biochemical actions of the toxin secreted by Vibrio cholerae. Based on this understanding it is possible to devise new techniques for the treatment and prophylaxis of cholera to complement those based on fluid replacement therapy and sanitation.

CHOLERA patients have characteristically watery diarrhoea which leads to dehydration and metabolic acidosis. If untreated, this fluid loss rapidly leads to death. The disease is caused by an intestinal infection with *Vibrio cholerae*. These bacteria adhere to and colonize the small intestine and secrete an exotoxin—cholera toxin—that binds to receptors on the mucosal cells and stimulates intestinal adenylate cyclase activity. The resulting increase in cyclic AMP then causes diarrhoea and fluid loss by inhibiting uptake of sodium chloride by the villi as well as by stimulating active chloride secretion by crypt cells¹.

Koch, who identified *V. cholerae* as the causative agent of cholera, had in 1887 already proposed that the disease was toxin-mediated but it was not until 1959 that the Indian scientists De² and Dutta³ convincingly demonstrated the existence of a cholera toxin. This was purified^{4,5}, and its effect on the adenylate cyclase-cyclic AMP system soon established⁶⁻¹⁰. Since then, activation of adenylate cyclase by cholera toxin has been shown to occur in most mammalian cell types, the structure-function relationship of the toxin has been defined, the cell membrane receptor identified and, most recently, the mode of action of the toxin on adenylate cyclase explained in considerable detail.

This knowledge of the cholera toxin has made it a useful tool for cell biologists, biochemists and physiologists interested in aspects of cell membrane and cyclic nucleotide research that are essentially unrelated to cholera. It has also suggested various possibilities for novel approaches to prevention and treatment of disease. My main intention here is to describe the cellular action of cholera toxin and to discuss the possible exploitation of this knowledge in the design of vaccines, receptor-prophylactic agents, and antisecretory drugs against cholera.

The cholera toxin molecule

Cholera toxin is a protein with two types of subunit: a single 'heavy' subunit of molecular weight (MW) 28,000 noncovalently attached to a 58,000-MW aggregate of 'light' subunits (Fig. 1).

The demonstration that choleragenoid, a protein immunologically related to cholera toxin and able to bind to intestinal epithelium without having toxic activity⁴, contains the same 'light' subunits as the toxin but lacks the 'heavy' subunit strongly suggested that the 'light' subunits are responsible for cell binding (B subunits) and the 'heavy' subunit for the direct toxic activity (A subunit)^{11–14}. Experiments with toxin subunit fractions, prepared by gel filtration in acidic buffer and dialysed to allow renaturation and reassociation of subunits, confirmed that B subunit bound strongly both to the cell and to the isolated cell receptors, but was nontoxic. Purified A subunit neither bound to nor was toxic for intact cells. However, A reassociated with B had both binding and toxic activity in various whole-cell systems ^{11–13,15,16}.

The requirement for membrane binding by the B subunits can be circumvented by using disrupted cells; in these conditions purified A subunit and also its A_1 fragment (see Fig. 1) can activate adenylate cyclase^{17–19}. Furthermore, the characteristic lag period of 10–60 min observed in intact cells before any effect of cholera toxin on adenylate cyclase is seen^{6–10}, essentially disappears in broken cells. Reduction of the disulphide bond between the A_1 and A_2 regions, but not the physical separation of the two fragments, seems to be necessary for the activity of A on adenylate cyclase²⁰.

The cholera toxin receptor

The first event in the action of cholera toxin on cells is the rapid, tight binding to receptors on the cell surface. Studies with $^{125}\text{I-labelled}$ toxin have shown that binding occurs almost instantaneously, is saturable and initially reversible 15,21 . The number of binding sites per cell varies widely with the cell type but affinity of binding varies very little $(K_{\rm A} \sim 1 \times 10^9 \, {\rm mol}^{-1})$ indicating that the receptor is the same for various cell types $^{21-23}$.

It is now known that the membrane receptor for cholera toxin is a specific ganglioside (Fig. 2). Van Heyningen $et\,al.^{24}$ observed that a crude ganglioside mixture inactivated cholera toxin; J.H. $et\,al.^{25}$, Cuatrecasas²¹ and King and van Heyningen²⁶ showed that this inactivation resulted from specific binding between the toxin and a single ganglioside, G_{M1} . G_{M1} neutralized cholera toxin in about equimolar proportions and gave a specific precipitation band with cholera toxin in gel-diffusion tests²⁵.

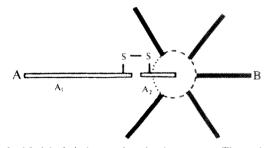

Fig. 1 Model of cholera toxin subunit structure. The toxin has one 28,000-MW A subunit and five 11,600-MW B subunits $^{11-16,29,62,102-107}$. The B subunits, which contain 103 residues 9 and 86 (refs 105, 106), are aggregated in a ring by tight, noncovalent bonds. The A subunit is linked to and partially inserted in the B ring through weaker noncovalent interactions 45 . A subunit, although synthesized as a single polypeptide chain (one gene) 108 , is usually 'nicked' between its two cysteine residues by bacterial protease(s) and thus splits into fragments A_1 (MW \sim 21,000) and A_2 (MW \sim 7,000) when treated with thiol-reducing agents $^{11-15,62}$. Reduction of whole toxin releases the A_1 fragment from the A_2 -5B complex, indicating that A is attached to the B ring by its A_2 portion 102,109 . Electron micrographs show the outer diameter of the B ring to be 90–100 Å, and the size of the separated A and B subunits as \sim 35 ×55 Å and \sim 24 × 30 Å (refs 110, 45).

Subsequent studies in several laboratories have provided further evidence that ganglioside $G_{\rm M1}$ is the natural biological receptor for cholera toxin.

- (1) Studies of various cell types, including small intestinal mucosal cells of different species, have demonstrated a direct relationship between the cell content of $G_{\rm M1}$ and the number of toxin molecules that the cells can bind^{22,27,28}. In each cell type studied there have been about five molecules of $G_{\rm M1}$ per toxin binding site²⁷, which supports data from *in vitro* fixation studies²⁹⁻³² that each toxin B subunit binds to one $G_{\rm M1}$ molecule.
- (2) Exogenous G_{M1} ganglioside can be incorporated into the cell membrane, there to act as a functional receptor. This was first shown by Cuatrecasas³³, who observed an increased cholera toxin-binding capacity and lipolytic responsiveness of fat cells which had been soaked in G_{M1} . Using ³H-labelled G_{M1} , J.H. et al. ²² demonstrated the incorporation of G_{M1} into epithelial membrane of small intestine from humans and other species and showed that the increase in G_{M1} was associated with a corresponding increase in the capacity of the intestine to bind cholera toxin. In vivo tests in rabbits showed parallel increases of G_{M1} and susceptibility of the gut to the diarrhoeogenic action of the toxin²². Incorporation of G_{M1} into transformed cells deficient in this ganglioside has restored cell responsiveness to cholera toxin^{34,35}.
- (3) Pretreatment of cell membranes with cholera toxin has been found to block specifically the membrane $G_{\rm M1}$ from reacting with galactose oxidase³⁶.
- (4) Incubation of certain tissues with V. cholerae sialidase increases the number of toxin-binding sites in proportion to the additional $G_{\rm M1}$ produced by the enzyme from more complex gangliosides in the membrane; cellular sensitivity to the toxin is simultaneously enhanced^{27,113-115}. However, V. cholerae sialidase has failed to create new receptors for cholera toxin in intestinal epithelium²² even though after extraction, the intestinal gangliosides are normally hydrolysed by this enzyme²². Thus intestinal epithelium seems to possess a means of preserving its structural integrity from enzymatic attack.
- (5) Chemical modifications of cholera toxin by various reagents have consistently and proportionally affected binding to cells and to plastic-adsorbed G_{M1} ganglioside³⁷.

Membrane penetration and activation of adenylate cyclase

As already indicated, the lag between cell binding of cholera toxin and activation of adenylate cyclase mainly reflects the time taken for the toxin A subunit to penetrate the cell membrane. In comparison, the generation of A₁ and the subsequent effect on adenylate cyclase are rapid events that occur in <1 min (ref. 17). The cell penetration process is poorly understood; the time it takes is markedly influenced by the incubation temperature and the composition of the cell membrane (J.H. et al., unpublished results). Lateral diffusion and capping of cholera toxin in the membrane have been demonstrated and have been proposed to be critical for action of the toxin^{38,41}. Lateral diffusion seems to have a much greater influence on the lag time in $G_{\rm MI}$ -poor cells than in those with more receptors. Thus, cell incorporation of exogenous G_{M1} significantly shortened the lag period in C6 cells which bind 7,000 toxin molecules per cell⁴², while no such effect was seen for mouse thymocytes (J.H. et al., unpublished results) which bind 150,000 toxin molecules per cell and exhibit a much shorter lag period³⁷

Moss et al.⁴³ and Tosteson and Tosteson⁴⁴ have shown that both cholera toxin and its B region can create pores in synthetic lipid bilayers containing G_{M1} ; however the observed capping of cholera toxin in viable cells suggests that the initial G_{M1} -toxin complex makes contact with an integral membrane protein. As discussed in detail elsewhere⁴⁵, the association of toxin with the membrane G_{M1} receptors might induce a conformational change in the B subunits, resulting in exposure of otherwise hidden hydrophobic B-subunit regions which then fuse with hydro-

phobic protein or lipid components of the plasma membrane. This could result in entry of the A subunit into the cell by one of at least three possible mechanisms. First, it is possible that the B subunits form a hydrophilic channel through the membrane, allowing A to pass; second, a channel for A subunit, may be built by the B subunits and an integral membrane protein; the third possibility is that a hydrophobic interaction between the A subunit and an integral membrane component may transpose A to the inner face of the membrane where intracellular glutathione would reduce the A_1 - A_2 disulphide linkage, thereby releasing A₁. Membrane-bound cholera toxin is partly endocytosed^{27,46}. Recent studies have suggested that for diphtheria toxin (the action of which resembles that of cholera toxin although the metabolic and clinical effects are very different⁴⁷), adsorptive endocytosis is required for membrane penetration and cytotoxicity at physiological pH; lysosomotropic agents protect the cells, probably by neutralizing the acid pH in lysosomes, thus preventing the acid-dependent conformational change of endocytosed toxin in secondary lysosomes that is necessary for the translocation of the diphtheria toxin A fragment^{48,49}. Lysosomotropic agents, such as ammonium chloride and chloroquine, should also be tested for their effect on the activity of cholera toxin.

The intracellular biochemical events that lead to activation of adenylate cyclase are known. Gill⁵⁰ showed that, in broken cell preparations, activation depends on NAD, undefined cellular cytosol factors and ATP, in addition to the A₁ fragment and cell membrane. Moss *et al.*⁵¹ showed that cholera toxin, like diphtheria toxin, has ADP-ribosyltransferase activity, that is, it catalyses the reaction:

NAD + acceptor protein \rightarrow ADP-ribose-acceptor protein + nicotinamide + H⁺

The protein that is ADP-ribosylated by cholera toxin has recently been identified as the guanyl nucleotide-binding component of the membrane-bound adenylate cyclase 52.53. Cassel and Selinger 4 have shown that adenylate cyclase is active while GTP is bound to the GTP-binding component but reverts to an inactive state as GTP is hydrolysed to GDP by GTPase; cholera toxin blocks the GTPase action which stabilizes adenylate cyclase in an active conformation. Alternatively, cholera toxin may stimulate adenylate cyclase by enhancing an exchange reaction in which stimulatory GTP replaces inhibitory GDP at a rate higher than that of hydrolysis of GTP to GDP 55

B subunit cholera vaccine

Can recent knowledge about cholera toxin be used to improve prevention or treatment of disease? Although the development of the highly successful water and electrolyte substitution therapy was essentially an empirical process, three rather more specific approaches have given promising results in animals and are now being used in clinical trials.

The first of these is the development of an oral cholera vaccine based on enterotoxin B subunit. In contrast to clinical cholera disease, which gives rise to long-lasting immunity. the wholecell cholera vaccines give only partial immunity for <6 months. Animal studies have shown that antitoxic and antibacterial cholera immunity cooperate synergistically in the gut giving a multiplicative protective effect by interfering with separate pathogenic events—toxin binding and bacterial adhesion and colonization. The whole-cell vaccines probably fail both because they lack any toxin-derived antigen and because the injection route may be relatively inefficient in stimulating local immunity in the gut mucosa.

Purified cholera B subunit, which spontaneously reassociates to the pentamer ring⁶⁰, is a logical 'toxoid' immunogen against cholera, especially for oral immunization. It is immunologically unrelated to A subunit^{13,29,62} and is a much stronger immunogen⁶³. Furthermore, isolated antibodies to B subunit have considerably higher cholera toxin-neutralizing activity than antibodies to the A subunit^{63,64}. The separation of B

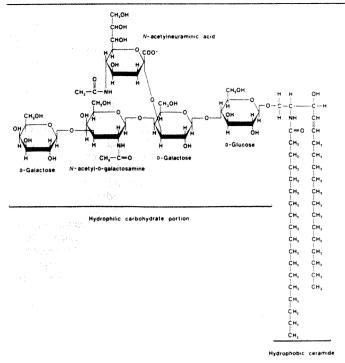

Fig. 2 Structure of the cholera toxin receptor, G_{M1} ganglioside. The oligosaccharide moiety of G_{M1} carries the binding determinants for cholera toxin, and studies have shown that both the terminal galactose and the sialic acid residues, positioned as in G_{M1} , are required for receptor activity 25,11 ; the removal or masking of any of these residues effectively inhibits the cholera toxin binding activity 25 . Decarboxylation of the sialic acid residue destroys the receptor activity of G_{M1} (ref. 30 and L. Svennerholm et al., in preparation), while oxidation with sodium periodate or exchange of the N-acetyl group by N-glycolyl does not affect activity (ref. 34 and L. Svennerholm et al., in preparation). The lipid moiety of G_{M1} is also important. A sufficiently long hydrocarbon chain is needed for stable fixation of cholera toxin 31,112 . Lyso- G_{M1} , in which the fatty acid has been replaced by an acetyl group, has been shown both to have intact toxin-binding activity 31 and to be even better than G_{M1} in promoting subsequent toxin-membrane interactions necessary for activation of adenylate cyclase 34 .

subunit from A excludes any risk of reversion to toxicity but does not lead to significant loss of protective antigen determinants⁶⁰. B subunit is particularly well suited to oral immunization because it retains the ability to bind to the intestinal epithelium, which has been shown to be important for stimulating mucosal immunity in animals, including local immunological memory⁶¹. Finally, as will be further discussed, B subunit given orally may also provide nonimmunological protection by blocking receptors before stimulating local immunoglobulin A (IgA) antitoxin formation. Purified B subunit is a strong protective antigen against experimental cholera in rabbits when given either alone or in combination with somatic antigens⁶⁰. It was recently tested⁶⁵ for its ability to stimulate mucosal immunity in humans; a single oral administration stimulated a marked local secretory IgA antibody response in 80% of the recipients. The response was comparable to that evoked in cholera patients by the natural disease⁶⁶. In further studies, two oral immunizations with a mixture of B subunit and whole-cell vaccine have produced secretory IgA antibody responses in intestine both to the toxin and the bacterial cell-wall lipopolysaccharide antigens in almost all people vaccinated⁶⁷. These results are promising but protective efficacy of an oral combined B subunit-whole cell vaccine in people living in areas in which cholera is endemic will require evaluation by field trials. The production of sufficient amounts of B subunit should not pose any problem, due to the recent development of affinity chromatography purification using a G_{M1} column⁶⁸.

Genetic methods may also supply *V. cholerae* strains which selectively lack the gene for the 'toxic' A subunit. By retaining the ability to colonize the intestine and produce immunogenic B subunit, such strains could be useful as live oral cholera vaccines. It must be borne in mind, however, that any living vaccine of this sort will require thorough testing for stability, and lack of side

effects before it can be used in humans. In that respect it is disappointing that the first such V. cholerae strain (Texas star)⁶⁹, produced diarrhoea (although usually very mild) in about 20% of recipient American volunteers in spite of producing no detectable holotoxin when grown in vitro⁷⁰.

Receptor-specific interference with toxin binding

The second rational approach to cholera prophylaxis is based on the identification of $G_{\rm M1}$ as the toxin receptor. In theory, the oral administration of large amounts of $G_{\rm M1}$ or a structural analogue could be used to prevent binding of the toxin to cell receptors. Alternatively, cell receptors could be blocked by the nontoxic B subunit.

Development of cholera was prevented by giving $G_{\rm M1}$ to rabbits³⁰, but for prophylactic medical use, enough $G_{\rm M1}$ would have to be given to ensure an excess in relation to the amount of toxin produced by the cholera vibrios in the gut. Most clinical isolates of V, cholerae produce considerably less than $1~\mu g~ml^{-1}$ of cholera toxin when grown in vitro, and toxin concentrations in diarrhoeal fluid of patients have not been found to exceed $0.2~\mu g~ml^{-1}$ (refs 71, 116). Assuming a daily production of $\sim 10~nmol$ of cholera toxin in $\sim 5~l$ of small intestinal juice, neutralization of the toxin should be accomplished by a similar amount of $G_{\rm M1}$. To avoid the incorporation of oral $G_{\rm M1}$ into intestinal cells, which would increase their susceptibility to cholera²², the toxin could be adsorbed onto medical charcoal⁷¹, or covalently coupled to cellulose powder, for example (L. Svennerholm et al., in preparation).

As G_{M1} cannot deactivate toxin that has already bound to the intestine, it would be expected to have a preventive rather than a curative effect. However, in a recent clinical trial the amount of G_{M1} -charcoal that completely bound the free, luminal V, cholerae enterotoxin also reduced purging in the early stage of disease⁷¹. The most likely explanation for this observation is that, because of the constant and rapid regeneration of gastrointestinal cells, there are always new cells available to bind cholera toxin or to be protected by an agent that binds the toxin. This is probably the first instance in which a specific receptor has been used to interfere with an infectious disease. However, it should be emphasized that the observed effect of G_{M1} -charcoal was too transient and incomplete to be practically useful; rather, G_{M1} given orally would possibly be useful for prophylaxis in high-risk groups such as family contacts of cholera patients.

As the B subunit of cholera toxin binds tightly to G_{M1} receptors but has no toxic activity, it might be possible to block the intestinal receptors by occupying them with purified B subunit protomer. It has been shown that pretreatment of the gut of rabbits with 0.5 μ g of B subunit per cm completely protected the animals from experimental cholera after challenge with high doses of active cholera toxin^{22,72,73}. A human trial is conceivable now that it is technically possible to prepare purified B subunit in sufficient quantities⁶⁸; as little as ~100 μ g of B subunit could theoretically block all available receptors, based on the determination of amounts of G_{M1} in human intestinal epithelium²². B subunit is both safe and specific, and might prevent manifestation of disease while inducing local antitoxic immunity and allowing the infection to elicit an antibacterial immune response. In contrast to prophylactic G_{M1} , B subunit would also block toxin which is secreted in close proximity to the microvilli.

Antisecretory drugs

The third approach, intended for therapy rather than prophylaxis, aims at specifically reversing the toxic action after the cholera toxin has become bound to the intestinal cells. During the past decade oral hydration therapy by means of appropriate glucose-electrolyte solutions has greatly simplified the treatment of dehydrating diarrhoea, making effective therapy feasible in situations where intravenous treatment facilities are limited or unavailable 74-76. This treatment takes advantage of the presence of an uptake mechanism for sodium in conjunction

with certain organic solutes, including glucose, which is not regulated by cyclic nucleotides and thus is unaffected in cholera and other forms of enterotoxic diarrhoea⁷⁷. In patients with mild or moderate dehydration the success rate with oral therapy is very high, usually more than 90%. However, in severely affected patients purging often occurs at such a high rate that balance cannot be maintained by oral fluid only, and intravenous replacement of fluid is essential for survival. Drugs that could reduce the rate of fluid loss in the severe dehydrating diarrhoeal diseases would obviate the need for much intravenous therapy and thus could play an important part in the management of severe diarrhoea. Such antisecretory drugs would need a high therapeutic index so that they could be used without extensive medical supervision, and they would have to be compatible with oral fluid therapy.

Based on present understanding of the biochemical events initiated by cholera toxin, possibilities for specific intervention include: (1) prevention of entry of A subunit (although not clinically useful as this event occurs before the onset of symptoms); (2) use of purines and their analogues to alter the NADase action of cholera toxin; (3) use of alternative acceptors, such as arginine or imidazoles, for the ADP-ribose generated by the toxin; (4) reversal of the ADP-ribose-adenylate cyclase association; and (5) removal of ADP-ribose by a specific ADPribosidase. While some of these approaches have reversed the action of cholera toxin in vitro in broken cell systems, kinetic and other considerations make the likelihood of success of inhibiting this stage of the secretory process in vivo extremely remote?

There seem to be considerably greater opportunities for inhibiting the action of cholera toxin subsequent to the ADP ribosylation step by interfering with cyclic AMP formation or metabolism, or by modulating electrolyte-translocating mechanisms of the intestinal membrane. Several drugs have been found to inhibit secretion induced by cholera toxin in experimental animals, for example, chlorpromazine⁷⁹ and certain related compounds⁸⁰, nicotinic acid⁸¹, aspirin⁸², indomethacin⁸³, ethacrynic acid⁸⁴, propranolol⁸⁵, lidocaine⁸⁶ and berberine¹¹⁷ (for review see ref. 118). Chlorpromazine is the best studied of these drugs. In mice, treatment intramuscularly or enterally with 1-4 mg of chlorpromazine per kg body weight completely inhibited the intestinal secretion caused by cholera toxin, Escherichia coli LT, prostaglandin E1 or dibutyryl cyclic AMP⁷⁹. In similar doses, chlorpromazine reversed fluid loss in piglets with enterotoxinogenic E. coli diarrhoea⁸⁷. In adult patients with severe cholera, treatment with chlorpromazine either perorally or intramuscularly, in a single dose of 1 or 4 mg per kg, rapidly and drastically reduced the purging volumes by -65% (ref. 88). The patients became mildly sedated, were more comfortable, and had no nausea or vomiting. A follow-up clinical trial has shown that treatment of children with 1 mg per kg chlorpromazine increased the success rate of oral hydration therapy in patients with severe cholera⁸⁹

The mechanism of antisecretory action of chlorpromazine is not fully known; however, it does seem to be confined to the intestinal epithelium^{79,90,91}. Chlorpromazine was selected for testing because of its ability to inhibit hormonal stimulation of cyclic AMP formation in various tissues^{92,93}; both the cholera toxin- and fluoride-stimulated adenylate cyclase activities of the intestinal mucosal membrane of chlorpromazine-treated mice are suppressed⁷⁹. However, the activity of the protein kinase of mucosal membranes is also reduced, suggesting multiple effects of chlorpromazine⁷⁹. In the brain, chlorpromazine and other phenothiazines are known to inactivate calmodulin and to interfere with transfer of calcium across the nerve-cell membrane94; if these effects occur in the intestine, they could lead to inhibition of secretion 91,119. The action of chlorpromazine on calmodulin could possibly be linked to an inhibitory effect on adenylate cyclase.

Perspective

It has been estimated that each year about 1,000 million episodes of acute diarrhoea occur in children under 5 years of

age in Asia, Africa and Latin America, resulting in 5 million deaths. In many developing countries one-third to one-half of infant mortality can be attributed to diarrhoeal diseases. Even in the older age groups diarrhoeal episodes are frequent causes of severe illness and death^{95,96}.

Cholera is not the most prevalent of the diarrhoeal diseases, but it causes the most severe fluid loss and thus is responsible for a large proportion of life-threatening illness and death during the cholera season in endemic areas. Furthermore, research during the past decade has also made it clear that cholera is a prototype of diarrhoeal diseases caused by other enterotoxinproducing bacteria, especially E. coli⁹⁷. Taken together, the enterotoxic enteropathies probably account for at least one-half of dehydrating diarrhoeal illnesses. Knowledge of the structure and function of cholera toxin has been the main stimulus and provided guidelines for recent research in elucidating the aetiology and pathogenesis of these related diarrhoeas. Diagnostic assays for *E. coli* LT based on toxin-induced cyclic AMP manifestations in animals or cell lines 98,99, or more recently, on immunological 100 or receptor-immunological methods 101 are based on similar methods for cholera toxin.

Although clean water supplies and safe disposal of human sewage would effect a dramatic reduction in cholera and other diarrhoeal disease, these two goals cannot be achieved in many areas for decades. If effective vaccines could be developed, they would no doubt be important components of national control programmes against diarrhoeal disease. The same holds true for drugs that could prevent or reduce fluid loss in enteric infections and thus alleviate the need for intravenous treatment.

Here I have described some theoretically possible approaches to counteract cholera toxin by immunological or pharmacological means. While each of these methods have been effective against cholera in animal studies, and, to the limited extent to which they have been tested, have also given promising results in man, much more research is needed to define their place, if any, in future prophylaxis and treatment of cholera. They should be regarded merely as starting points for further development. For example, in relation to vaccine development there is a need for better understanding of factors regulating the magnitude and duration of intestinal antitoxic as well as antibacterial immunity. With regard to receptor-prophylactic agents, basic research should be directed to identify specific binding or blocking agents for cholera vibrios which might cooperate synergistically with those for toxin. In the case of antisecretory agents, the aim should be to find drugs which effectively depress secretion but lack the sedative action of chlorpromazine. However, it is gratifying that cholera toxin research has now reached the stage where rational counteractive methods can be both formulated on the basic molecular knowledge, and, most importantly, be evaluated in controlled clinical and field trials.

I thank the many colleagues who contributed much to the cited work from this laboratory. I particularly thank Professor Lars Svennerholm and his group for close collaboration on all aspects of G_{M1} ganglioside as receptor for cholera toxin: Drs Ann-Mari Svennerholm and Ivar Lönnroth for aspects relating to immunity and vaccine development, and antidiarrhoeal action of phenothiazines, respectively; Dr William B. Greenough and his staff at the International Centre for Diarrhoeal Disease Research, Dacca for the clinical trials; Institut Merieux, Lyon and SBL, Stockholm, for technical collaboration and for preparing G_{M1}-charcoal and B subunit for the clinical tests; and Dr Charles Wadsworth for his criticisms of the manuscript and helpful comments.

High noble metal concentrations in a late Pliocene sediment

Frank T. Kyte*†, Zhiming Zhou* & John T. Wasson*†‡ *Institute of Geophysics and Planetary Physics, †Department of Earth and Space Sciences, ‡Department of Chemistry, University of California,

Los Angeles, California 90024, USA

A 2.3-Myr-old layer in a sediment from the Antarctic Ocean contains Ir and Au at levels comparable with those at the Cretaceous-Tertiary boundary. A sizable fraction of the noble metals is contained in vesicular, millimetre-sized polymineralic grains that closely resemble ablation debris from chondritic meteorites, and there is little doubt that the noble metals resulted from the accretion of a large extraterrestrial object. No massive extinctions or other evidence of environmental stress seem to be associated with this accretionary event.

THE accretion of kilometre-sized asteroids to the Earth must have a significant impact on the terrestrial ecosystem. Such encounters have been a stochastic source of stress to the biosphere, influencing evolution and extinction rates. Recent discoveries of Ir (ref. 1) and other extraterrestrial siderophiles ¹⁻⁴ in sediments at the 65-Myr-old Cretaceous-Tertiary boundary have supported the hypothesis that encounters of sufficient magnitude can lead to the simultaneous extinction of many species. These discoveries have also illustrated that at least some types of encounters deposit a measurable geochemical signal in the sedimentary record.

If the Earth accreted a massive body at the end of the Cretaceous 65-Myr ago, then other bodies of similar size should have left their signatures elsewhere in the geological record. From relationships given by Grieve and Dence⁵ and an assumed mean impact velocity of 20 km s^{-1} we calculate the relationship $N = 6.7 \times 10^{-7} r^{-2}$ where N is the cumulative number of bodies impacting the Earth each year and r (in km) is the radius of the body. This relationship indicates that ~43 bodies should have impacted the Earth since the Cretaceous. Wetherill⁶ gives a similar estimate. This relationship is based on crater counts, and if preimpact breakup occurs in an appreciable fraction of the cases, the impact rate could be higher⁷.

A logical step in establishing the link between major changes in the terrestrial environment and the accretion of kilometresized bodies is to find and characterize other sediments having enhanced concentrations of noble metals. In this article we report our first success, the discovery a large enhancement of noble metals near the Pliocene-Pleistocene boundary in an Antarctic Ocean deep-sea core. Core USNS Eltanin 13-3 was selected because Crocket and Kuo⁸ found Ir concentrations in one 210-cm long section that were three times higher than those in other sections from the same core. It was also intriguing that the base of this 210-cm unit was associated with radiolarian extinctions, geomagnetic reversals, and climatic change⁹.

Experimental results

Eltanin core 13-3 is a muddy diatomaceous ooze collected in 1964 at a depth of 5,090 m at 57° 00' S and 89° 29' W. It has been heavily sampled and is dried out in some areas. In the region of interest (780-800 cm) it contains ~65% diatoms and radiolaria and 30% clay with ~5% quartz, heavy minerals and trace Mn micronodules. It consists of a pale brown ooze with strings or sedimentary clasts of pale orange diatomaceous ooze. The sedimentation rate as determined by palaeomagnetic stratigraphy is approximately constant at 3.3 $\mu m \ yr^{-1}$ (refs 8, 9). A total of 71 samples, each 3-4 cm in length were taken for a continuous section from 645 to 875 cm, extending from 10 cm above to 10 cm below the interval in which Crocket and Kuo⁸ found the noble-metal enhancement. Two additional control samples were taken from 551-553 and 946-948 cm. Samples of 150-200 mg were irradiated for 60 h at 10¹⁴ neutrons cm⁻² s⁻¹ and analysed by instrumental neutron activation analysis (INAA); results are listed in Table 1. Iridium was the only noble metal that could be determined; the control samples and those in the ranges 645-771 and 797-875 mm were below our detection limit of 0.5 ng per g. On discovery of high Ir (1-9 ng per g) levels in samples from the 771-797 cm level, another 14 samples (600-750 mg) were irradiated for 3 h at a flux at 2×10^{12} neutrons cm⁻² s⁻¹ in the UCLA reactor and Au and Ir were determined by radiochemical neutron activation analysis (RNAA) using the procedure described previously4.

Our RNAA analyses on a second set of samples were carried out to confirm the Ir anomaly and to measure Au concentrations in this horizon (Table 1). We also attempted to analyse for Os, Pt, Pd and Re in two samples, but because of the low neutron flux and low noble metal concentrations we obtained only upper limits with CI-chondrite-normalized element/Ir ratios >2. These are not diagnostic for distinguishing between chondrite groups, but we plan to determine these elements in another experiment. Poor chemical yields caused significant errors on a few Ir data, but in general there was a good correlation between

Au and Ir. Our background Ir values agree well with the value of $0.20~\rm ng$ per g determined by Crocket and Kuo⁸; our background Au value of $\sim 0.32~\rm ng$ per g is about half their value. We cannot readily explain this discrepancy. Our RNAA and INAA Ir values often differed by as much as a factor of 2. As discussed below, these discrepancies probably reflect sample inhomogeneity rather than analytical problems. The band proved wider in the RNAA section than anticipated on the basis of the initial INAA survey. Later, in longer counts an Ir concentration of 2.3 ng per g was found in another sample (35) which may extend the enriched layer another 7 cm above the RNAA data set.

Because the sample sizes were about four times larger we have greater confidence in our RNAA data. Figure 1 shows the RNAA Ir and Au concentrations in the peak and in several background samples. Using a background of 0.20 and 0.32 ng per g for Ir and Au, respectively, and a bulk dry density of the sediment of $2 \, \mathrm{g \, cm^{-3}}$, the net Ir and Au fluences integrated across the horizon are 100 and $63 \, \mathrm{ng \, cm^{-2}}$, respectively. The resulting Au/Ir mass ratio of 0.6 is higher than that in all groups of chondrites except the EH (formerly designated E4 and E5) enstatite chondrites ¹⁰.

By chance, two large (1.5-2.0 mm) grains of Ir-rich material were found in INAA sample 42. Together with a minor amount of adhering clay they weighed 4 mg. Their Ir concentration was 160 ng per g, accounting for $\sim 40\%$ of the total Ir in this sample. In polished section these grains were observed to be highly vesicular ($\sim 50\%$) with a finely microcrystalline texture. This consisted of equant, $\sim 10~\mu \text{m}$ euhedral silicates in a silicate matrix containing a sparse submicrometre opaque phase. Qualitative analysis by electron microprobe indicated that the silicates were zoned Ni-bearing olivine in a Ca, Al, Si-rich matrix.

It seems that these materials correspond to the olivine-magnetite-glass assemblage typical of cosmic spherules and debris produced by the laboratory ablation of chondrites¹¹.

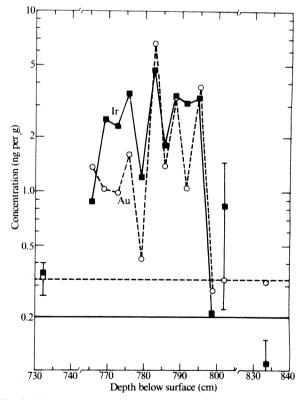

Fig. 1 Concentrations of Ir and Au in Eltanin core 13-3. Background levels (shown by horizontal lines) are 0.20 ng per g Ir and 0.32 ng per g Au; maximum concentrations in the peak in the depth range 765-800 cm are ~25 times the background levels. The integrated flux of Ir is 100 ng cm⁻², of Au 63 ng cm⁻². The observed Au/Ir ratio is similar to values in EH enstatite chondrites. The 70% uncertainty limits are shown for three of the lowest Ir values are examples of the precision at these levels. More exact information regarding the precision is given in Table 1.

Table 1 Concentrations of Ir and Au measured at various depths of Eltanin core 13-3

	9	INAA	RN	IAA

Relative uncertainty limits are $\pm \le 10\%$ except as indicated.

Their texture, equant olivine grains set in a vesicular matrix, is found in cosmic spherules separated from sea sediments, but is less common than textures such as barred olivine or platy brickwork¹¹. A > 147-µm sieve fraction of another 1g of sample 42 contained a 1-mm particle with similar petrographic properties and four others in the size range 0.2-0.5 mm. The sample heterogeneity mentioned above is probably the result of statistical fluctuations in the number of large grains of chondritic debris through the section.

Only one particle was roughly spherical in outline, the rest having irregular shapes. All particles had severely etched rims, with only their cores retaining an apparently unaltered texture. The obvious dissolution of particle rims may have resulted in a post-depositional redistribution of a fraction of the noble metals in the horizon. Our observed concentrations of ≥ 3 mg cm⁻³ chondritic debris contrasts with typical influxes of ablation debris of 'cosmic spherules' > 0.2 mm of 30 ng cm⁻³ based on a worldwide accretion rate of 90 tons yr⁻¹ (ref. 12) and the reported sedimentation rate.

Discussion

There seems little doubt that the noble metals in our Antarctic Ocean core are of extraterrestrial origin, as indicated by their roughly chondritic Au/Ir ratios, and by the remarkably high concentration of chondritic debris. This debris reaches concentrations about five orders of magnitude higher than expected in sediment having the observed sedimentation rate. The observed particles have petrographic textures of a rare type regularly observed in typical collections of cosmic spherules.

We interpret this horizon as resulting from a single, accretionary event. Presently available information does not allow us to distinguish between oceanic impact and atmospheric ablation as the source of these materials, but similarities of the large 'spherules' to materials produced in artificial ablation experiments¹³ suggests that they were produced by atmospheric ablation of asteroidal or cometary material. Total breakup above the solid or liquid surface of the Earth apparently requires that the material be highly friable as is inferred to be the case for some cometary materials. Microtektites have not been found in sieved samples of our horizon and thus are much less abundant than 'ablation' debris. This probably indicates that at most a minor fraction of the noble metal enhancement can be associated with crater ejecta.

The integrated flux of 80–100 ng Ir cm⁻² is ~0.15 g cm⁻² H₂O-free CI material or an initial horizon ~0.5 mm thick. We suspect that bioturbation has spread out an initially thin, concentrated horizon, although this is difficult to confirm observationally in such an old, heavily sampled core. The 30–40 cm thickness of the enriched layer is similar to thicknesses of microtektite horizons¹⁴ and to bioturbation mixing lengths inferred in core E13-3 in palaeontological studies¹⁵. Rapidly deposited horizons of this type might, in fact, provide interesting markers for estimating effects of bioturbation and of trace-element transport during diagenesis.

element transport during diagenesis.

The 80-100 ng Ir cm⁻² in this horizon is similar to the maximum reported for the Cretaceous-Tertiary boundary at various European sites^{1,2,4}. Thus, if this horizon is worldwide, the mass of accreted chondritic matter is comparable with that of the Cretaceous-Tertiary materials. However, the high abundance of millimetre-sized ablation (or impact) debris suggests that the site of this core is near the location where the meteoroid entered the atmosphere and/or impacted with the surface of the ocean, thus the fluence at distant locations may be significantly lower.

The late Pliocene noble-metal-enrichment is probably not too localized, otherwise it would probably not have been discovered in the few cores analysed by Crocket and Kuo⁸. A major event showering debris over a wide area is a much more likely mechanism for producing discoverable concentrations of this magnitude. Considering that the proposed 0.5 mm-thick horizon was deposited after settling through 5 km of water, and the differential settling times of the particles (~8 h for 2 mm compared with ~11 h for 1 mm diameters) in currents which today are ~0.7 km h⁻¹ (ref. 16) would spread this debris over a very large area even if it originated from a point source. We propose a minimum projectile diameter of 20 m, enough material to produce similar enrichments over only 10 km². We suspect that it must have been significantly larger.

Crocket and Kuo⁸ found no Ir enhancement at the same time range in core Eltanin 17-10 that was collected ~2,800 km away. Their sample containing the corresponding time interval, however, covers a depth range 800-1,400 cm, nearly three times longer than that in 13-3. For this reason their negative result may not be significant. Additionally, palaeomagnetic studies indicate that the horizon would be near the base of the sampled interval and might even overlap into the next interval (1,400-1,585 cm) which has slightly higher Ir (0.42 ng per g).

In contrast to noble metal-enriched sediments at the Cretaceous-Tertiary boundary, there is no major palaeoenvironmental crisis associated with this noble metal horizon. Hayes and Opdyke9 report that radiolarian species vary with depth in core 13-3, but no dramatic change is associated with the peak in Ir concentrations at the 770-800 cm depth. In contrast to the Cretaceous-Tertiary boundary, the nearby Pliocene-Pleistocene boundary does not represent a major biostratigraphic hiatus. Definition of the base of the Pleistocene is now generally accepted as the base of the Calabrian stage in the type section at La Castella, Italy, dated at ~1.8 Myr (refs 17, 18). Earlier attempts to define this boundary based on the onset of glaciation (continental or polar) resulted in proposed boundaries ranging in age from 0.5 to 4 Myr (ref. 18); major cooling occurred as early as 4.0 Myr (ref. 17). Palaeomagnetic evidence indicates that our horizon occurs at ~2.3 Myr. If, in fact, this horizon proves to be worldwide it is an important marker bed for late Pliocene stratigraphy, and might warrant use as the Plio-Pleistocene boundary.

Clearly it is important to extend our studies to sediments of the same age from other localities. Although our best projection based on the available facts is that notice metal concentrations at distant locations will be less than those in core 13-3, we do expect to find that the horizon covers a significant fraction of the Earth. Additionally, the discovery of a second significant horizon during the most recent 65 Myr of Earth history suggests that we can find others of similar magnitude throughout the Cenozoic. If so, this will lead to major improvements both in our knowledge regarding the flux of large bodies to the Earth and in

^{* 70%} confidence limits $\pm 10-19$ %.

^{† 70%} confidence limits $\pm 20-39\%$.

^{‡70%} confidence limits ±40-79%.

our ability to correlate marine sediments from widely separated locations.

If this horizon does prove to be worldwide in extent, the absence of major extinctions associated with this late Pliocene event becomes an important fact bearing on models explaining the massive Cretaceous-Tertiary extinctions in terms of environmental effects associated with a major influx of extraterrestrial matter.

Controls of RNA splicing and termination in the major late adenovirus transcription unit

Göran Akusjärvi & Håkan Persson

Department of Microbiology, University of Uppsala, The Biomedical Center, Box 581, S-751 23 Uppsala, Sweden

The major late adenovirus promoter is active early after infection, selectively producing messenger RNAs coding for polypeptides with molecular weights of 55,000, 52,000 and 14,000. This selective expression suggests that a differential splicing pattern occurs at the transition from early to late viral gene expression. Activation of the late promoter and splicing of the 55, 52K mRNAs does not require newly synthesized virus polypeptides.

TRANSCRIPTION from the adenovirus genome late in infection initiates predominantly at the promoter located at map coordinate 16.3 (ref. 1) and proceeds in a rightward direction for about 28,000 base pairs (bp)². This long viral transcript is processed into five families of messenger RNAs (mRNAs), each family having co-terminal 3' ends3-5 (L1-L5, Fig. 1A) and each mRNA containing a tripartite leader, encoded at coordinates 16.6, 19.6 and 26, spliced onto the body of the mRNA^{6,7}. The genes for two low-molecular-weight RNAs (VA RNA; and VA RNA_{II}), transcribed by RNA polymerase III, have been located close to coordinate 30 on the viral genome^{8,9}. Three mRNA species, originating from the major late transcription unit, have been mapped by electron microscopy in the vicinity of the VA RNA genes¹⁰ (Fig. 1A).

The lytic cycle of adenovirus infection is divided into two functionally distinct phases, the early phase preceding and the late phase beginning with the onset of virus DNA replication. It has been assumed that the major late transcription unit is activated at the shift from early to late phase. However, a low level of rightward-reading transcripts proximal to the late promoter has been detected in the nuclei of early infected cells11, and truncated cytoplasmic RNAs originating from the late promoter have also been found early in the infectious cycle by electron microscopy^{12,13}. Transcription studies using purified restriction fragments carrying the major late promoter suggest that virus-specific components are not necessary for initiation at this promoter site, at least in vitro 14.15. We now demonstrate that the major late transcription unit is active at early times of infection, producing selected transcripts. This indicates a novel, virus-regulated abundance control of mRNA production.

Viral RNAs from region L1

To study the expression of RNAs from the major late transcription unit, we first determined the structure of the r strandspecific RNAs encoded in region L1. Cytoplasmic RNA prepared late after adenovirus type 2 (Ad2) infection was hybridized to the entire viral DNA and treated with S₁ endonuclease. The S₁-resistant hybrids were separated on an alkaline agarose

gel and subsequently transferred to a nitrocellulose filter. Hybridization of the filter to a 32P-labelled probe specific for region L1 (Fig. 2) shows that five major RNA species (Fig. 1B, lanes a-e) had been present in the cytoplasmic RNA preparation. Species b, c and e have previously been identified by electron microscopy¹⁰. The S₁ analysis revealed two novel species, a and d. The length of species a suggests that it represents a co-linear transcript of the DNA template from the third leader segment up to the poly(A) addition site at position 38.5 (ref. 3). Late viral cytoplasmic RNA was selected by hybridization to a BamHI-HindIII fragment specific for region L1. The selected RNA was then used to determine the structure of region L1 RNAs. The RNA was first hybridized to the HindIII-B fragment¹⁶ of the viral DNA (coordinates 17.0-31.5), ³²P-labelled by nick translation followed by S₁ endonuclease treatment¹⁷ This analysis revealed two major protected species, 520 and 440 nucleotides long (Fig. 2B, lane a). Further mapping of protected fragments showed that VA RNA_I, VA RNA_{II} and a 200nucleotide read through product of the VA RNA_I gene (V₂₀₀)¹⁸ were present in the selected RNA. In the same way, the bands of 73 and 89 nucleotides were shown to correspond to the second and third segments of the common tripartite leader 19,20. The presence of the leader segments in the RNA species which protect fragments of sizes 520 and 440 nucleotides implies that the common tripartite leader is spliced onto their 5' end and that they originate from the major late transcription unit^{6,7}. When the HindIII-B fragment was protected with the selected RNA, digested with S₁, the ³²P-labelled BamHI-HindIII probe hybridized to a 520-nucleotide band, but not to one of 440 nucleotides (data not shown). This demonstrates that the body of the RNA species extends 520 nucleotides into the HindIII-B fragment, and that the 440-nucleotide fragment is encoded elsewhere on the genome (see below).

Recognition signals for splicing coincide with sites for termination of RNA polymerase III

To map the leader-body splice junction at the nucleotide level, we used a modification of the original Berk and Sharp S_I method¹⁷. The ³²P-labelled *HindIII*-B fragment was cleaved with a restriction endonuclease, before hybridization to RNA. If a complementary RNA molecule extends across the restriction enzyme cleavage site, subsequent S₁ analysis will reveal two protected DNA fragments, which will add up to the length of the protected fragment obtained without cleavage.

Cytoplasmic RNA selected by hybridization to the BamHI-HindIII fragment was used for this analysis. Figure 1C shows the cleavage sites for restriction enzymes used to cleave the HindIII-B fragment. Cleavage with endonuclease PvuII resulted in the disappearance of the 520-nucleotide band, and the appearance of two new bands, 275 and 245 nucleotides long (Fig. 2B, lane b). The larger band represents the distance between the PvuII and HindIII site at coordinate 31.5. Therefore, the RNA body extends 245 nucleotides to the left of the PvuII site, positioning the leader-body splice site at coordinate 30.0. Cleavage of the DNA fragment with endonuclease SacII (Fig. 2B, lane c) generated three bands of 125 (coordinates

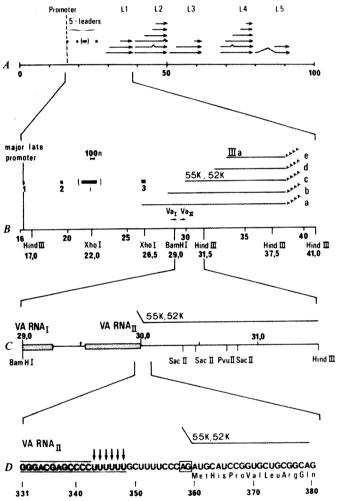

Fig. 1 Organization of the adenovirus 2 genome. A, Schematic diagram of RNAs originating from the major late transcription unit. The 20 identified RNA species are divided into five families (L1-L5), the members of each family having a common position for the poly(A) addition sites. The 5 leaders are spliced onto each of the 20 RNA bodies. The i leader found on a fraction of the RNAs is shown within brackets. B. Enlargement of region 16.0-41.0 encoding the major late promoter site at map coordinate 16.3, the common 5' leaders and the L1 3'-co-terminal family. The position of the VA RNA genes is shown as well as our revised RNA map for region L1. The position of restriction endonuclease cleavage sites relevant to this study are also shown. The mRNAs to which we have assigned translation products are indicated. C, Enlargement of fragment BamHI-HindIII encoding the 5 sequences of the 55, 52K mRNA body. The position of restriction endonuclease cleavage sites used in this study are indicated. D. The leaderbody splice junction of the 55, 52K mRNA. The nucleotide sequence is taken from ref. 9 and the numbering is from the BamHI cleavage site at position 29.0. Arrows indicate the position of the heterogeneous 3' end of VA RNA_{II} and the box shows the A·G dinucleotide invariably found at the 3' side of intervening sequences²¹. The predicted amino-terminal sequence of the 55K and 52K polypeptides is also shown.

Table 1 Early transcription of regions L1, L2 and L3 of the Ad2 genome

Coordinates DNA probe	Region	Length (kilobases)	c.p.m. in hybrid	Molarity
31.5-37.3	L1	2.0	240	1.0
41.0-50.1	L2	3.2	58	0.15
52.6-59.6	L3	1.5	187	1.0

Ad2-infected HeLa cells (500 FFU per cell) were resuspended at 5×107 cells per ml at 4 h.p.i. The cells were labelled with 500 µCi ml-1 of 3H-uridine for 10 min at 37 °C, collected on frozen phosphate-buffered saline and nuclear RNA prepared33. Nuclear RNA from an equivalent amount of cells was hybridized to various Ad2 DNA restriction fragments cloned in the bacterial plasmid pBR322. The cloned fragments were adsorbed to nitrocellulose filters and hybridization was carried out at 65 °C in 6×SSC buffer (1×SSC is 0.15 M NaCl, 15 mM sodium citrate). After hybridization the filters were washed extensively in 2×SSC buffer and treated with pancreatic ribonuclease (20 µg ml-1) for 1 h at 37 °C. Hybridized RNA resistant to the nuclease treatment was measured by liquid scintillation counting. Hybridization to filters containing the pBR322 plasmid were used as background hybridization. This was in all cases fewer than 20 c.p.m. and has been subtracted from each value. The results are the mean from two independent experiments. The length in kilobases was calculated from the size of the Ad2 restriction fragments, assuming that the whole fragments were transcribed. Molarity was calculated by dividing the c.p.m. in hybrid by the length of each fragment and normalizing to 1.0 for the L1 probe (coordinates 31.5-37.3).

30.83-31.5), 235 (30.47-30.83) and 118 nucleotides (splice junction to 30.37), confirming that the splice junction is located at coordinate 30.0. The 5'-end splice site was confirmed by S_1 analysis using a 5'-end-labelled DNA probe (Fig. 2C). The band corresponding to the entire DNA probe is derived from RNA species a and b as they both extend leftward of the BamHI cleavage site at coordinate 29.0.

The genes for the VA RNAs are located close to coordinate 30 on the viral genome^{8,9}. An artefactual cutting site may therefore be created during the S₁ analysis through displacement of the RNA body by VA RNA hybridizing to the same DNA template. To exclude this possibility, RNA was selected on fragment *HindIII-J* (coordinates 37.3–41.0), which is located outside the genes for the VA RNAs. S₁ analysis of this RNA generated the same pattern of bands as did RNA selected on fragment *BamHI-HindIII*, but the bands corresponding to the VA RNAs are missing (Fig. 2B, lane f). This demonstrates that the splice site is not due to VA RNAs hybridizing to the DNA sequences representing the splice junction.

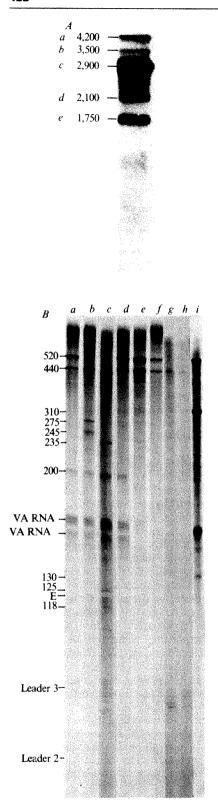

Because almost all known splice sites follow the G·T-A·G rule²¹, and because the nucleotide sequence in this region only contains one A·G dinucleotide, the site at which the third leader segment is spliced on to the RNA body is likely to be located at nucleotide 361 in Fig. 1D. The splice site for this RNA species is thus separated from the termination signal for VA RNA transcription⁹ by only 11 nucleotides (Fig. 1D). This compressed organization of processing signals suggests that the T-cluster, terminating transcription of VA RNA_{II}, also serves as a recognition signal for the enzyme(s) that cleave and ligate the tripartite leader to the RNA body.

Using blot hybridization to analyse DNA protected by BamHI-HindIII-selected RNA from S_1 digestion, the total size of the RNA body was estimated to be 2,900 nucleotides (not shown). From its size and genomic location we conclude that this RNA corresponds to RNA species c (coordinates 30.0-38.5) from region L1 (Fig. 1B).

Identification of an additional leader segment on region L1 RNAs

Electron microscopy of RNA-DNA hybrids has shown that a fraction of late cytoplasmic RNAs from the L1 co-termination family contains an extra leader segment from coordinates 22.0 to 23.2. The 440-nucleotide band observed by S₁ analysis may correspond to this extra leader segment.

The origin of this band was studied by the S₁ endonuclease assay using RNAs selected by hybridization to the BamHI-HindIII fragment. The ³²P-labelled HindIII-B fragment was cleaved with endonuclease XhoI before hybridization to the RNA and subsequent S₁ endonuclease treatment. The 440-nucleotide band was absent after this treatment and instead two

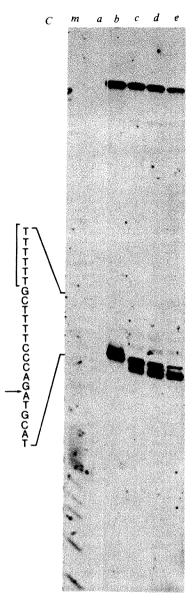

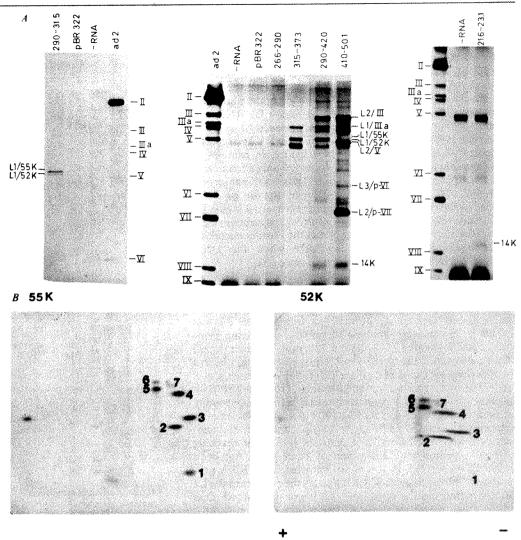

Fig. 2 S₁ endonuclease mapping of late adenovirus cytoplasmic RNA. A, 10 µg of late cytoplasmic RNA, 10 µg of tRNA and 2 µg of Ad2 DNA were mixed precipitated and dissolved in $10 \mu l$ of 50 mM PIPES pH6.4, 0.4 M NaCl, 1 mM EDTA and 80% formamide (buffer A). The DNA template was denatured by incubating the mixture at 70 °C for 10 min, followed by a hybridization for 3 h at 57 °C. The hybridization was terminated by the addition of 400 µl of an ice-cold buffer containing 30 mM NaAc pH 4.4, 4 mM ZnSO4 0.28 M NaCl, 5 µg of single-stranded calf thymus DNA and 5% glycerol. Then 225 units of endonuclease S₁ (Sigma) were added and the reaction mixture further incubated for 20 min at 37 °C. The S_1 cleavage was terminated by the addition of 50 µl S₁ stop solution (3 M NaAc, 80 mM EDTA and 10 µg tRNA) and 800 µl ethanol. The precipitated material was collected by centrifugation and dissolved in 20 µl of a buffer containing 50 mM NaOH, 1 mM NaOH, 1 mM EDTA, 2% Ficoli and market dyes, and separated electrophoretically on a 2% alkaline agarose gel34. After electrophoresis, the gel was soaked in 1 M Tris-HCl pH 7.5, 0.6 M NaCl for 10 min at room temperature and the S₁-protected fragments transferred to a nitrocellulose sheet as described by Southern³⁵. The nitrocellulose filter was subsequently hybridized in 6 × SSC, 3 × Denhardt and 0.5% SDS for 12 h at 65 °C with a 32P-labelled recombinant plasmid containing an insert of the HindIII-I fragment (coordinates 31.5-37.3) of Ad2 DNA¹⁶. The filters were washed in 0.2 × SSC, 0.5% SDS at room temperature for several hours, followed by a 15-min incubation at 65 $^{\circ}\mathrm{C}$ and additional washes at room temperature. The blots were analysed by autoradiography at -70 °C using a DuPont intensifying screen. The HindIII fragments of Ad2 DNA run in a parallel slot on the agarose gel were used as size markers. a-e Relates the S1 protected DNA fragments to the L1 mRNAs. B, Cytoplasmic RNA (as specified below) was mixed with 0.04 µg of a recombinant plasmid containing the *Hin*dIII-B fragment (coordinates 17.0-31.5) of Ad2 DNA16, 32P-labelled by nick translation. The mixture was ethanol precipitated and dissolved in 10 µl of buffer A. The subsequent denaturation, hybridization and S₁ endonuclease treatment were as described above. The precipitate was dissolved in 10 µl of a buffer containing 80% formamide, 1 mM EDTA and marker dyes. Electrophoretic separation was on thin 8% polyacrylamide gels containing 7 M urea and the ³²P-labelled bands were visualized by autoradiography. As size markers, ³²P-labelled ΦX174 DNA, cleaved with endonucleases HaelII and HindII, was included in the gel. In lanes b, c, d and i the HindIII-B clone was cleaved with restriction endonucleases before S₁ treatment. The DNA fragments were mixed with RNA and processed as described

above. Lane a, uncleaved DNA; lane b, PvuII; lane c, SacII; lane d, SaII; lane i, XhoI-cleaved DNA. The RNA used was: in lanes a, b, c, d and i, RNA purified by hybridization selection o on fragment o on f

new bands of 310 and 130 nucleotides were detected (Fig. 2B, lane i). A similar analysis using endonuclease SalI (cleavage sites 26.0 and 26.6) did not cleave the 440-nucleotide band (Fig. 2B, lane d). This shows that the 440-nucleotide band is derived from sequences located around the XhoI cleavage site at coordinate 22.0 (Fig. 1B). The size and location of the 440-nucleotide band suggest that it is identical to the extra leader, designated the i leader, previously identified by electron microscopy¹². As the RNAs used in the S_1 analysis were selected on DNA fragments outside the coding region for the i leader, the results suggest that it is covalently attached to the RNA molecules. RNA selected on fragments BamHI-C (coordinates 41.0-

59.0) and BamHI-A (coordinates 59.0–100) also generated the 440-nucleotide band after S_1 analysis (Fig. 2B, lanes g, h). This demonstrates that the i leader is present on at least a fraction of RNAs derived from all regions of the major late transcription unit. Densitometer tracing of the 520- and 440-nucleotide bands (Fig. 2B, lane a) indicates that there are two types of L1 RNAs, differing with respect to their 5'-leader segments. Type I RNAs have the structure 'leader 1, 2, 3 RNA body', and comprise \sim 40% of the total population, while type II mRNAs have the structure 'leader 1, 2, i, 3, RNA body' and comprise \sim 60% of the total. The 520-nucleotide long band and the leader fragments 2 and 3 were all present in equimolar concentrations.

Fig. 3 In vitro translation of hybridization selected mRNAs. A, Late cytoplasmic Ad2 RNA³⁸ was purified by hybridization to restriction fragments of Ad2 DNA on nitrocellulose immobilized filters³⁶. The hybridization-selected RNAs were translated in a reticulocyte cell-free system and the translation products were analysed by SDS-polyacrylamide gel electro-phoresis³⁸ (SDS-PAGE). The gels were analysed by fluorography. The HindIII restriction fragments were cloned in the plasmid pBR32216 and the hybrid plasmids were used for selection. Hybridization to the bacterial plasmid, pBR322; was used as a control for the specificity of selection. The endogenous synthesis in the cell-free system is shown in slots indicated by -RNA. Ad2 denotes here and in sub-sequent figures a ³⁵S-methioninelabelled Ad2 marker virus. Coordinates for restriction fragments used for hybridization selection are shown at the top of the figure. Restriction fragments used were as follows: SacI-M and -N (21.6-23.1), SalI-BamHI (26.6-29.0), BamHI-HindIII (29.0-31.5),HindIII-I (31.5-37.3), BamHI-D HindIII-D (29.0-42.0), *HindIII-D* (41.0-50.1). The left panel represents a 10% polyacrylamide gel and the right panels 13% polyacrylamide gels. B, Tryptic fingerprint analysis of the 55K and 52K polypeptides. Messenger RNA selected hybridization to fragment BamHI-HindIII (coordinates 29.0-31.5) was translated in a reticulocyte cellfree system in the presence of 35Smethionine. translation products were separated on a 10% SDS-polyacrylamide gel and the 55K and 52K polypeptides were

excised from the gel. Eluted polypeptides were oxidized with performic acid and digested with TPCK-treated trypsin³⁹. Tryptic peptides were separated by electrophoresis in the first dimension followed by ascending chromatography in the second dimension. ³⁵S-methionine-labelled tryptic peptides were visualized by autoradiography.

Polypeptides encoded in region L1

To test whether the RNA species encoded in region L1 code for polypeptides, late cytoplasmic RNA selected on the BamHI-HindIII fragment was used to programme an in vitro translation system. The selected RNA directed the synthesis of two polypeptides with molecular weights of 55,000 (55K) and 52,000 (52K). In addition, the third member of the L1 3'-co-terminal family, polypeptide IIIa²², was detected when RNA was selected by hybridization to fragment HindIII-I (coordinates 31.7-37.3) (Fig. 3A). RNA selected on fragment BamHI-D (coordinates 29.0-42.0) directed the synthesis of the 55K, 52K and IIIa polypeptides from region L1 and polypeptide III from region L2 (Fig. 3A), while the L2 polypeptides III, pVII and V were detected with RNA selected on fragment HindIII-D (coordinates 41.0-50.1). RNA selected on fragment SalI-BamHI (coordinates 26.6-29.0) did not yield any polypeptides (Fig. 3A). This region is absent in all the L1 RNA molecules except in species a and b in Fig. 1B. Interestingly, a 14K polypeptide was synthesized from RNAs selected by hybridization to all DNA probes covering regions L2-L5 (Fig. 3A).

Together, these results demonstrate that the 55K and 52K polypeptides are encoded by mRNA species c, mapping between coordinates 30.0 and 38.5 (Fig. 1B), and that polypeptide IIIa is encoded by mRNA species d or e (coordinates 33.5-38.5). We tentatively assign polypeptide IIIa to mRNA species e (coordinates 33.5-38.5) based on the enhanced accumulation of this species late in infection (see below). RNA selected on the viral r-strand directed the synthesis of the 55K

and 52K polypeptides, confirming that the mRNA is transcribed in a rightward direction (not shown).

The structural relationship between the 55K and the 52K polypeptides was investigated by tryptic fingerprint analysis. A very similar but not identical set of 35 S-labelled peptides was obtained (Fig. 3B), suggesting that these two polypeptides are structurally related. They may therefore be encoded on the same mRNA and their size difference may reflect a post-translational modification which occurs in vitro. We cannot, however, exclude the possibility that the 52K polypeptide is encoded by a minor fraction of species c which has an internal splice in the mRNA body.

Presence of the *i* leader alters the translation of the mRNA

The 55, 52K mRNA was selected by hybridization to fragments SacI-M and -N (coordinates 21.6–23.1) which cover the region of the genome encoding the i leader (not shown). This result is expected because around 60% of the 55, 52K mRNA has the structure 'leader 1, 2, i, 3, RNA body'. However, cell-free translation with SacI-M- and -N-selected mRNA did not result in the synthesis of the 55K and 52K polypeptides (Fig. 3A), but instead, produced a 14K polypeptide; this suggests that mRNA species containing the i leader do not translate the body of their mRNA sequences. Because eukaryotic ribosomes usually initiate translation at the AUG codon closest to the 5'-end²³ of the mRNA, the results suggest that an AUG triplet is encoded within the i leader itself. Late cytoplasmic RNA selected on

DNA fragments distinct from the i leader but covering regions L2-L5, followed by in vitro translation, also resulted in the synthesis of the 14K polypeptide (Fig. 3A). A fraction of these L2-L5 mRNAs contain the i leader, suggesting that the 14K polypeptide is encoded within the i leader itself. Late cytoplasmic RNA selected on DNA fragments covering region L1 showed very little synthesis of the 14K polypeptide. However, this polypeptide was detected when the region L1 RNA was prepared from cells maintained in the presence of cytosine arabinoside (ara C) (Fig. 5B). Most of the L1 mRNAs prepared from ara C-treated cells contain the i leader, in contrast to mRNAs prepared from untreated cells, where only a fraction of the L1 mRNAs contain this leader¹². Thus, our inability to detect the 14K polypeptide among the translation products specified by late RNA selected on fragments covering region L1 may simply reflect a low quantity of RNA containing the i leader. Rigorous proof for the theory that the i leader encodes a 14K polypeptide will become available when the DNA sequence has been determined; this is in progress.

An abundance control for late mRNA production

The temporal appearance of mRNAs from region L1 was studied by S_1 nuclease analysis of poly(A)-containing cytoplasmic RNAs isolated 7, 16, 20 and 30 h post-infection (h.p.i.) (Fig. 4). At 7 h.p.i., the 55, 52K mRNA (species c, Fig. 1B) was abundant and species d and e barely detectable. Species a, b, d and e began to accumulate at late times (16 and 20 h.p.i.). Species e accumulated progressively during infection, becoming the predominant mRNA from L1 at 30 h.p.i., while the amount of species d increased markedly to 16 h.p.i. and then declined. Species a and b remained at a constant level after reaching maximal accumulation. The origin of band x has not been further characterized, as it was not detected in all RNA preparations. The mechanism which regulates the changes in the L1 mRNA pattern during virus infection is not understood. One

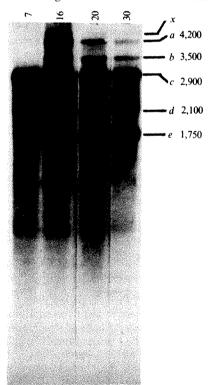

Fig. 4 Demonstration of an abundance control by S_1 endonuclease blot analysis. 2 μg of Ad2 DNA, 5 μg of oligo-d(T)-selected cytoplasmic mRNA isolated at 7, 16, 20 or 24 h.p.i. and 15 μg of tRNA were mixed, precipitated and dissolved in 10 μ l of buffer A. The hybridized RNA was analysed by the S_1 blot assay described for Fig. 2A using a 32 P-labelled recombinant plasmic containing the HindIII-I fragment (coordinates 31.5–37.3) of Ad2 DNA as a probe. a-e Relates the S_1 protected DNA fragments to the L1 mRNAs (Fig. 1B). Numbers at the tops of the slots indicate h.p.i.

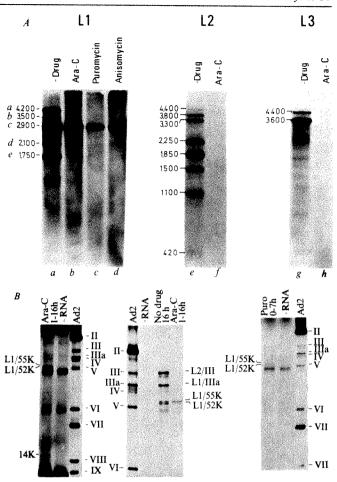

Fig. 5 Analysis of cytoplasmic RNA isolated from cells maintained in the presence of metabolic inhibitors. A, 10 µg of cytoplasmic RNA (specified below), 10 µg of tRNA and 2 µg of Ad2 DNA were mixed, precipitated and analysed by the S₁ blot technique described in Fig. 2 legend. Subsequent hybridization was with ³²P-labelled recombinant plasmids containing inserts of fragment HindIII-I (coordinates 31.5-37.3) (region L1), HindIII-D (coordinates 41.0-50.1) (region L2) and a 680-bp cDNA insert mapping between coordinates 58.8 and 60.7 (region L3). The RNA samples used are: lanes a, e and g, control RNA isolated from cells 16 h.p.i.; lanes b, f and h, RNA prepared from cells maintained in the presence of ara C (25 µg ml⁻¹) from 1 to 16 h.p.i. RNA isolated from cells treated with puromycin (100 μM) or anisomycin (100 µM) from the time of infection to 7 h.p.i. are shown in lanes c and d. The HindIII fragments of Ad2 DNA run in a parallel slot on the agarose gel were used as size markers. a-e Relates the S, protected DNA fragments to the L1 mRNAs (Fig. 1B). B, Cytoplasmic RNA prepared from cells maintained in the presence of ara C (25 µg ml⁻¹) from 1 to 16 h.p.i. or puromycin (100 µM) from the onset of infection to 7 h.p.i. was selected by hybridization to fragment HindIII-J (coordinates 37.3-41.0). The selected mRNAs were translated in a reticulocyte cell-free system and the in vitro synthesized products were analysed by SDS-PAGE. The middle panel represents a 10% polyacrylamide gel, the two other panels are 13% polyacrylamide gels. The gels were analysed by fluorography. The RNA used for hybridization selection is indicated at the top of the figure. -RNA; no RNA added.

possible explanation is a differential splicing of the nuclear precursor transcript at early and late times after infection. Alternatively, the temporal appearance of the mRNAs may be due to virus-regulated changes in mRNA stability during the infectious cycle.

mRNAs from the major late promoter early after adenovirus infection

Detection of the 55, 52K mRNA as early as 7 h.p.i. suggested that the major late promoter is active before the onset of virus DNA replication. To confirm this, we examined RNAs synthesized in the presence of inhibitors which block virus DNA replication. Cytoplasmic RNA, isolated from cells maintained in the presence of ara C, was analysed by the S_1 nuclease assay. Hybridization to a DNA fragment specific for region L1 revealed only species c (Fig. 5A, slot b). Cytoplasmic RNAs

from regions L2 and L3 were not detected in the absence of virus DNA replication (Fig. 5A).

The selective accumulation of mRNA species c early in infection was also demonstrated by in vitro translation of RNA selected on fragment HindIII-J (coordinates 37.3-41.0). RNA isolated from cells treated with ara C yielded the 55K and 52K polypeptides and the 14K polypeptide, whereas cytoplasmic RNA from untreated cells obtained late in infection directed the synthesis of polypeptides III, IIIa, 55K and 52K (Fig. 5B).

Role of newly synthesized viral proteins in major late adenovirus promoter activation

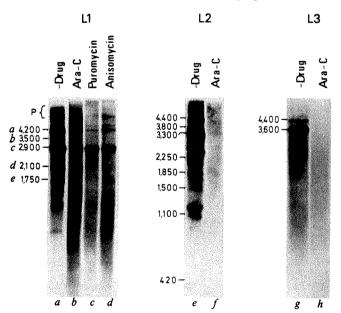

To determine whether virus-specified early proteins are necessary for activation of the major late promoter, we analysed RNA samples prepared from cells maintained in conditions of stringent inhibition of protein synthesis²⁴. Treatment with puromycin or anisomycin from the start of the infection still resulted in selective accumulation of the 55, 52K mRNA (Fig. 5A, slots c, d). Furthermore, the 55, 52K mRNA synthesized in the absence of virus protein synthesis was functionally active when assayed in an *in vitro* translation system (Fig. 5B).

The selective expression of the 55, 52K mRNA from the major late transcription unit, in the absence of protein synthesis, suggests that the activation of the major late promoter, and the splicing and polyadenylation of the 55, 52K mRNA, do not require newly synthesized viral polypeptides. After completion of this study, Lewis and Mathews²⁵ reported similar results concerning the synthesis of the 55K and 52K polypeptides.

Truncated nuclear RNAs accumulate in the absence of virus DNA replication

When virus DNA replication is blocked, cytoplasmic RNAs from region L2 and L3 are undetectable. To determine if the nuclear precursors of these RNAs were present we examined nuclear RNA preparations.

On S₁ analysis of nuclear RNA prepared from cells 18 h.p.i. and not treated with metabolic inhibitors, all cytoplasmic RNA species specific for regions L1, L2 and L3 were detected in nuclear RNA preparations, although the relative abundances in the nucleus differed from those in the cytoplasm. Nuclear

accumulation seems to be greatest for the longest RNAs from each 3'-co-terminal family. The most prominent nuclear RNAs accumulated from region L1 were species a and c (Fig. 6, slot a), but a cluster of long RNAs, ranging in size from 6,000 to 8,000 nucleotides, was also detected, probably representing precursor molecules originating from the major late transcription unit²⁶. Large nuclear RNA species also accumulated from region L2 (bands of 4,400, 3,800 and 3,300 nucleotides, Fig. 6, slot e). Region L3 accumulated nuclear RNAs corresponding to the 4,400- and 3,600-nucleotide long pVI and hexon mRNAs²⁷ (Fig. 6, slot g). The 4,400-nucleotide band seen with the L2 and L3 probes corresponds to the same RNA species, as the pVI mRNA from region L3 extends ~300 nucleotides into the HindIII-D fragment²⁷.

Analysis of nuclear RNAs, prepared from cells where virus DNA replication was blocked, showed a selective accumulation of RNA species a and c from region L1 (Fig. 6, slots b-d). We also detected RNA molecules co-linear with the DNA template from the promoter site at coordinate 16.3 up to the poly(A) addition site at coordinate 38.5. Similar results were obtained when protein synthesis was inhibited with puromycin or anisomycin from the start of virus infection.

Nuclear RNA species from region L2 were barely detectable in RNA preparations from cells treated with ara C (Fig. 6, slot f) and only the 3,300-nucleotide long RNA species was discerned. Nuclear RNA from region L3 was not detected (Fig. 6, slot h), demonstrating that, in the absence of virus DNA replication, RNA beyond coordinate 59 does not accumulate.

To determine the length of the transcript from the major late promoter at early times after infection, cells were pulse-labelled for 10 min at 4 h.p.i. with ³H-uridine and nuclear RNA was prepared. The nuclear RNA was hybridized to cloned DNA fragments covering different regions of the major late transcription unit. Table 1 shows that transcripts from region L1 were 5-10-fold more abundant than from region L2 early in infection. However, there was marked hybridization to the probe from region L3, probably reflecting the fact that the leftward transcript for early region 2 terminates within the double-stranded DNA probe used for the L3 region (cited in ref. 28). The low hybridization to region L2 compared with region L1 together with the S₁ analysis of nuclear RNA suggest that transcription terminates within the L2 region at early times of infection. Similar results were obtained with pulse-labelled RNA from cells treated with anisomycin from the start of virus infection (not shown). The length of the transcript from the major late promoter early in infection was independently determined by Shaw and Ziff²⁹.

Conclusions

We have analysed RNAs originating from the major late transcription units of adenovirus type 2, at different times after infection. The results suggest that the shift from the early to the late phase of virus replication does not involve activation of the major late promoter at map coordinate 16.3. Rather, this promoter is already active during the early phase. Furthermore, the synthesis of viral polypeptides is not required for its activation, as mRNA from the major late promoter is produced under stringent inhibition of protein synthesis24. A preferential synthesis of mRNA species c from region L1 (Fig. 1B), which encodes the two structurally related polypeptides of molecular weight 55,000 and 52,000, was observed at early times. The lack of detectable amounts of L2 and L3 mRNAs may be explained by the fact that nuclear transcripts produced at early times of infection seem to terminate within the L2 region. Therefore, the shift from the early to the late phase of virus replication may involve a mechanism which allows the production of larger transcripts from the major late transcription unit. This mechanism could be mediated by virus-coded factors which associate with the RNA polymerase, by a change in the nucleoprotein structure of the DNA template, or by DNA replication providing single strands of virus DNA which may serve as a more efficient template for late transcription.

The selective accumulation of the 55, 52K mRNA early in infection may be explained by a virus-regulated abundance control of late mRNA production. At different times after infection the individual mRNAs from region L1 (Fig. 1B, species a-e) are differentially expressed. The first mRNA to accumulate in the cytoplasm is the 55, 52K mRNA, whereas at late times of infection, species e, encoding virion polypeptide IIIa, is the most abundant. Thus, the selective appearance of the 55, 52K mRNA early in infection may reflect a regulation of the abundance of region L1 mRNAs. This regulation is probably accomplished by virus-regulated changes in the splicing pattern of the transcript but may also depend on virus-regulated changes in cytoplasmic mRNA stabilities. However, the latter alternative is unlikely because the mRNA stability seems to be enhanced at late times of infection30

As RNA polymerase III transcription normally terminates within a stretch of U residues³⁴, and the termination signal for VA RNA_{II} transcription is separated by only 11 nucleotides from the splice junction of the 55, 52K mRNA (Fig. 1D), the

acceptor site of the 55, 52K mRNA has a U-rich sequence directly upstream from its splice junction. This sequence arrangement resembles splice sites found in several eukaryotic genes³². If the abundance control of late mRNA production involves virus-controlled splicing events, the appearance of the 55, 52K mRNA at early times of infection may reflect a preference for the acceptor site of the 55, 52K mRNA.

The 55, 52K mRNA exists at about equal frequency in two forms which differ by the presence of the i leader. In the RNA species which have an insertion of the i leader within the tripartite leader, the expression of the polypeptides from the mRNA body seems to be blocked. This suggests that insertion of the i leader, by splicing, controls gene expression at the level of translation.

We thank Ms M. Pettersson for technical assistance, Dr M. Perricaudet for the gift of the cDNA clones, Drs L. Philipson, U. Pettersson and V. Tate for help in the preparation of the manuscript and Ms M. Gustafson and C. Sjöholm for secretarial help. Diversity of germ-line immunoglobulin V_H genes

David Givol, Rina Zakut, Kim Effron, Gideon Rechavi, Daniela Ram & Justus B. Cohen

Department of Chemical Immunology, The Weizmann Institute of Science, Rehovot 76100, Israel

The sequences of four embryonic mouse immunoglobulin V_H genes have been compared. All genes end at codon 98 and code for a hydrophobic signal peptide of 19 residues interrupted at codon -4 by an intron of 83 base pairs. Substitutions occur in all gene segments but at a significantly higher frequency in the hypervariable regions. The data suggest an evolutionary basis for the diversity of immunoglobulin genes. Divergence resulted also in a termination codon in two of the genes, suggesting that part of the V gene repertoire cannot be expressed unless some correction mechanism is available.

IMMUNOGLOBULINS are composed of heavy and light chains. Their variable region (V_L and V_H) is confined to the amino-terminal domain of the molecule and comprises the antibody-combining site. The combining site is formed by three hypervariable segments of the V region which contain the complementarity-determining residues (CDR1-3) for antigen^{1,2}. The variable region of the light chain is encoded in the germ line by three separate gene segments: the leader (L), coding for a hydrophobic signal peptide which is not present in the mature protein, the variable segment (V_L) and the joining segment (J_L)³⁻⁵. The variable region of the heavy chain is encoded by four gene segments: the leader (L), the variable segment (V_H), the 'diversity' segment (D) and the joining segment (J_H). The D and J_H segments contain the codons for CDR3 whereas the V_H segment contains the codons for CDR1 and CDR2 (refs 6, 7). It has been shown that there are only four J_H gene segments⁷. Amino acid sequence data indicated that the genes for the variable regions are organized in subgroups which evolved by gene duplication^{8,9}. Expansion and contraction of these subgroups and evolutionary accumulation of mutations contribute to the diversity of these genes^{8,9}. Recent analysis at the DNA level demonstrated multiple genes in subgroups of both $V_{\rm L}^{\ 10}$ and $V_{\rm H}^{\ 11}.$

A basic problem in immunology is the extent of inherited diversity compared with the diversity generated somatically in the V genes. The V_H segment is present in two different DNA environments during the life of the antibody-forming cells, the embryonic and the mature environments. During lymphocyte differentiation DNA rearrangement joins V with D and J (V-D-J joining) to form the active V_H gene⁶. As evidence for recombination of V_H with each of the four J_H segments has been found^{6,7} and the joining is flexible, part of the V-region diversity in CDR3 is generated somatically by this recombination. These recombination events involve the cutting and joining of DNA

Table 1 Per cent substitution in V_H-gene segments

		Non-coding	segments				Coding se	gments	
		Tron tooning		Signal 1	peptide	F	R	CI	OR
Clone	5' region	Intron	3' region	R	s	R	S	R	S
pCh108B pCh104 pCh111	15 23.8 23.8	15.7 25.3 21.7	20.0 37.9 37.9	7.0 12.3 10.5	1.8 1.8 5.3	4 5.34 6.2	4 4.4 5.8	11.6 30.4 27.5	0 1.5 4.3

The per cent substitution was calculated as compared with the pCh108A sequence. In the coding region substitutions are divided into replacement (R) and silent (S) substitutions. The 3' region was calculated beyond the recombination signals. FR, framework regions of V_H . CDR, complementarity-determining residue regions of V_H .

segments and may be accompanied by other enzymatic activities, such as error-prone repair 12,13 , which result in further substitutions along the $V_{\rm H}$ segment. The question arises as to whether the hypervariability found in CDR1 and -2 pre-exists in the germ line or is generated in the new DNA environment only after somatic rearrangement.

To analyse this question we isolated and sequenced four mouse $V_{\rm H}$ genes isolated from a BALB/c mouse embryo DNA library ¹⁴. These genes belong to the $V_{\rm H}$ II subgroup. Their nucleotide sequence shows 80–90% homology with the cDNA clone of mouse myeloma MPC11 heavy chain ¹⁵ that was used as a probe in isolating these genes. The data indicate that the hypervariability in the regions corresponding to CDR1 and -2 is already present in the embryonic non-rearranged $V_{\rm H}$ genes, suggesting that the substitution in hypervariable regions is a result of an evolutionary process. The sequence also shows that two of the $V_{\rm H}$ genes contain termination codons within their coding region and may be considered pseudogenes. Perhaps this is the price paid for keeping a multiple gene family like the immunoglobulin V genes.

Characterization of V_H-containing clones

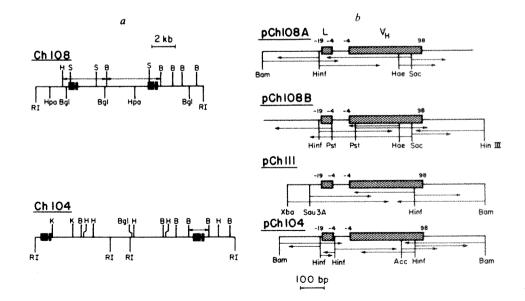

We isolated eight cross-hybridizing clones by screening our mouse embryo DNA library with plasmid $pV(11)^2$ which contains V_H cDNA derived from myeloma MPC11 (ref. 15). Three of these clones that showed strong cross-hybridization were selected for sequencing. One of them (Ch111) contained only one V_H gene; the others contained two V_H genes. In clone Ch108 the two V_H genes are located on a single EcoRI fragment with a spacing of ~ 7 kilobases (kb) (Fig. 1a) suggesting that V_H genes which belong to the same subgroup are close to one another in the genome. Clone Ch104 contained two V_H genes on

separate EcoRI fragments with a spacing of ~ 12 kb. The appropriate segments containing the V_H genes were subcloned in pBR322 and subjected to DNA sequencing, according to the strategy shown in Fig. 1b. The sequence of ~ 800 base pairs (bp) was determined for each of the genes, and compared with that of MPC11 cDNA to locate the coding region. The overall structure of all four genes demonstrates their germ-line nature as the coding sequence ends prematurely at codon 98 and contains neither D nor J segments. The codon corresponding to amino acid 1 is preceded by a sequence that codes for a signal peptide 16.17 of 19 amino acids which is interrupted at codon ~ 4 by an intron of 83 bp.

Sequence of the 5'-noncoding and leader region

Figure 2 depicts the sequence of the four mouse embryonic V_H genes upstream from codon 1 of the mature protein, in comparison with MPC11 cDNA sequence 15. It is clear that the V_H genes, although homologous, are variable in the region corresponding in part to the 5'-untranslated region of the mRNA. Hence, the variability is not confined to the V region, but extends into the 5'-untranslated region. Thus heavy-chain mRNA has a variable 5'-untranslated region while the 3'untranslated region is constant¹⁸. The sequence coding for the 19 residues which compose the hydrophobic signal polypeptide of the precursor heavy chain is separated at residue -4 (Gly) by an intron of 83 nucleotides which starts with GT and ends with AG. The size of this intron in all four genes is identical and differs by 2 nucleotides from the size of another mouse V_H intron⁷ and by 21 nucleotides from a human V_H intron which is 104 bp long¹⁶. It is significant that the location of this intron at codon –4 is identical in mouse $V_{\kappa}^{5,20}$, V_{λ}^{21} and $V_{H}^{6,7}$, as well as in

Fig. 1 Restriction enzyme maps of the mouse DNA inserts in clones Ch108 and Ch104 (a), and strategy used in sequencing of the subclones pCh108A, pCh108B, pCh111 and pCh104 (b). Cleavage sites were determined by single and double digestion of DNA with various restriction enzymes and by the endlabelling method of Smith and Birnstiel³³. The DNA segments between arrows in a were subcloned in pBR322. Sequence determination was by the chemical degradation method³⁴ of end-labelled fragments. End-labelling was done at the 3' end by site filling of 5'-protruding ends with reverse transcriptase. The reaction mixture (20 µl) contained 1-5 μ g of DNA fragments, 20 μ Ci of one or two $[\alpha^{-32}P]$ deoxynucleoside triphosphates and 5 units of reverse transcriptase, and was incubated at 37°C for 30 min. Blunt-ended fragments were labelled at the 3' end

using DNA polymerase (n.Klenow) and the appropriate $[\alpha^{-32}P]$ dNTP. 3'-protruding ends were labelled with $[\alpha^{-32}P]$ cordycepin triphosphate and terminal deoxynucleotidyl transferase³⁵. Enzymes used: RI = EcoRI; B = BamHI; H = HindIII; Bgl = BglII; K = KpnI; S = SacI, Hpa = HpaII; Hae = HaeIII; Acc = AccI; Hinf = HinfI; Pst = PstI; Sau = Sau3A. In b the numbers above the schemes represent codons for amino acids.

Fig. 2 Sequence of the 5' segment of four embryonic V_H genes including the codons for the signal peptide. Identical nucleotides are represented by dashes, insertions are introduced above the line and an empty space indicates a deletion. The region between parentheses was not determined (ND). Amino acid residues predicted by the nucleotide sequence are given above the line of the codons. The insert of MPC11 (M11) cDNA clone 15 begins at codon - 14 and the coding sequence of the signal peptide was determined in this cDNA clone (unpublished work).

the human V_H gene¹⁹. The homology at the two ends of the introns (first 30 bp and last 25 bp) in our genes is much greater than that in the middle part. The sequence of another reported V_H intron⁷ is significantly different (50% substitution) from the four sequences shown here (18-25% substitution) and indicates that V_H genes of different subgroups have diverged markedly from one another. The coding sequence for the signal peptide is not identical within the subgroup and the per cent substitution is similar to that of the V_H-coding region. However, comparison with sequences coding for signal peptides in V_H genes of other subgroups^{6,7,22} shows a greater divergence from our genes. The accumulation of mutations is proportional to the divergence time of the genes, and our comparison indicates that the leader sequence is part of the V_H duplication unit. Note that the middle highly hydrophobic region of this predicted amino acid sequence (residues -15 to -3) is very similar in all four genes and changes are more significant at the two ends of the sequence coding for the signal peptide.

The data also show that clone pCh108B has a substitution which changes the first Met (ATG) into Ile (ATA). Unless there is some correction mechanism, the mRNA of this gene may not be translated into an active protein. The validity of this substitution was checked in the original Ch108 clone.

Sequence of V_H -coding region and the recombination signals

Figure 3 shows the sequence of the V_H-coding region and the sequence downstream (3') from it. Comparison with the MPC11 sequence15 and with known JH segments7 demonstrates that all four genes end prematurely at Arg 98 which is exactly the end of framework III segment (no. 94 in the numbering system of Kabat et al.²³). Hence the D segment in the MPC11 V region starts at the beginning of CDR3 and contains eight amino acids (Gly-Ile-Tyr-Tyr-Asn-Ser-Ser-Pro). The V_H-coding sequence clearly demonstrates that substitutions occur preferentially at CDR regions (see later for comparison). When substitutions at the framework regions do occur, they are usually confined to the same position in all four genes. Most of these positions, such as codons 13, 16, 40, 41, 43 and 74, code for amino acid residues in which there is little structural constraint on replacements in the folded V domain. Comparison of these positions with homologous residues in three-dimensional models of V regions demonstrates that these residues are present in positions which

are completely exposed to solvent. It was shown at the protein level that amino acids which are buried in the domain are more conserved than those that are exposed to solvent 24,25 . Many of the substitutions in the framework result in two alternative codons causing conservative changes of amino acids. In several places the extent of diversity is not clear from this limited analysis. For example, codons 81-85 may be analogous to the fourth hypervariable region 26 of human V_H and the limited variations shown here may indicate the presence of this region in mouse embryonic genes.

At the 3' end of these V_H genes there are two recombination signals separated by 23 or 21 (pCH111) bp. The first signal

CACAGTG starts immediately after the codon for Arg 98 whereas in other cases there are 2 or 3 bp between $V_{\rm H}$ and this signal. This sequence is similar to that found in mouse $V_{\rm H}$ and $V_{\rm L}$ and in human $V_{\rm H}$ genes^{3,5-7,19} regardless of subgroups, and it is inversely complementary to a heptanucleotide present just 5' to the $J_{\rm H}$ region. As also noted by others, the second signal nonanucleotide is dA rich and contains more substitutions than the first signal. The sequence between the two signal oligonucleotides is highly homologous within this subgroup while the sequence of the 3' region beyond the second signal diverged more than other segments in these genes.

The immune V-gene repertoire may be rich in pseudogenes

Two of the genes, clones pCh104 and pCh111, contain termination codons at positions 39 and 94 respectively. Because there are some 40 substitutions in the V_H-coding region (294 bp long), a high proportion of these genes may have one substitution leading to a terminator. This is perhaps the price paid for keeping a multiple gene family (like immunoglobulin V genes) in evolution. The survival of the animal does not depend on any individual member of the V-gene family and selection operates on the entire V-gene repertoire to increase the number and diversity of V genes. The evolutionary accumulation of substitutions in V genes is essential for the generation of antibody diversity, and it is unavoidable that some of these genes will also acquire termination codons. The V genes which contain terminators may be pseudogenes²⁷. However, they differ from other pseudogenes reported. Recently Bentley and Rabbitts²⁸ described a human V_s pseudogene containing terminators,

deletions and insertions which result in changes of reading frame. Other pseudogenes also follow this pattern of changes^{29,30}. In contrast, pCh104 and pCh111 described here have one termination codon but otherwise conform to the sequence of a normal V_H gene. We suggest that these genes may be used if there is some correction mechanism. Such a mechanism may be the presence of suppressor tRNAs in lymphocytes or some other mechanism which allows reading through these terminators. Another possibility is that recombination between non-allelic V genes occurs at a high frequency^{10,31} so that their coding potential can be used to form active genes. It is of interest that the presence of pseudogenes in other gene families was recently explained as the consequence of gene duplication and divergence²⁹.

Evolutionary diversity of V_H genes

We analysed by DNA sequencing four cross-hybridizing embryonic mouse V_H genes which belong to subgroup II. The data indicate that these genes accumulated mutations in all their segments (5' region, leader, intron, V_H segment and 3' region), but differences were found in the extent of these substitutions in the various segments. We calculated the substitutions in the different parts of these genes as shown in Table 1. The per cent substitutions in noncoding regions (5', 3' and the intron) is higher than in the coding regions. However, the homology within

Fig. 3 Sequence of V_H segment and 3'-flanking region of the four embryonic genes and MPC11 cDNA. CDR regions are underlined. Recombination recognition signals^{6,7} at the 3' end of the coding segment are boxed. Amino acid residues deduced from the DNA sequence are given above the line of the codons. Ter indicates termination codons. Codon 98 corresponds to residue 94 in the numbering system of Kabat et al.²³ and it is the last residue of FRIII.

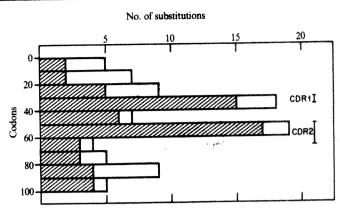

Fig. 4 Distribution of nucleotide substitutions along the $V_{\rm H^-}$ coding segments in all four genes sequenced. Bars represent total substitutions in blocks of 10 codons. Hatched areas represent total replacement substitutions.

noncoding segments of these genes is greater than the homology between these genes and genes of other subgroups. Moreover, the homology between neighbouring genes (pCh108A and pCh108B) is greater than the homology between them and the two other genes sequenced (pCh104 and pCh111). This suggests that V-gene duplication and diversity is a continuous evolutionary process, and the longer the divergence time, the more the mutations accumulate.

An important question is the extent of diversity in CDR regions of the germ-line V_H segment and whether this diversity occurs throughout evolution or after gene rearrangement. The data (Table 1 and Fig. 4) clearly indicate that the per cent substitutions in CDR is greater than in framework regions. Moreover, the per cent of replacement (non-silent) substitutions in CDR is significantly higher than that in the framework. Often more than one nucleotide in a codon is substituted, resulting in non-conservative replacement of amino acids. There are also invariable codons in CDR (like codons 32 in CDR1 and codons 51, 53, 56, 58, 60 and 61 of CDR2) which code for structural residues in CDR segments as suggested previously from the amino acid sequence 32. The data in Table 1 clearly show that the diversity in CDR1 and -2 is present in the germ line, and is generated throughout evolution. Evidence for additional somatic mutations in the hypervariable regions of V_A, V_K or V_H genes has previously been reported^{3,5,7,20}. We have not yet sequenced the embryonic gene that is expressed in myeloma MPC11. However, the sequence of the germ-line J region can be compared with its expressed counterpart. As there are only four germ-line JH-gene's egments, it is easy to locate somatic mutations in this region. A comparison of embryonic J_{H2}⁷ with that expressed in myeloma MPC11 shows a change in the fourth codon, from TAC(Tyr) to TCC(Ser).

This change is clearly an example of somatic mutation in CDR3, and is not merely a result of modulation of the joining site itself.

Conclusion

The DNA region containing the immunoglobulin V genes in a species is composed of several related families (subgroups) of genes. These undergo duplication and accumulate substitutions in all their segments in a process which is similar to the gene diversification that occurs among different species throughout evolution. The duplication unit of the V gene includes the sequence coding for the signal peptide. The entire V-gene

repertoire must be degenerate and contains nonsense mutations and pseudogenes. We may speculate that some correction processes, not yet found, have developed in lymphocytes to enable them to use the genetic potential encoded in such genes. The CDR regions, which are most essential for the function of the antibody, are hypervariable in the germ-line genes and after

γ Rays from the cosmic ray irradiation of local molecular clouds

M. R. Issa & A. W. Wolfendale

Physics Department, University of Durham, Durham DH1 3LE, UK

An analysis is given here of the flux of cosmic γ rays of energy above 100 MeV from the directions of 13 local molecular clouds. We show that only in a few clouds does the cosmic ray intensity need to exceed the value near the Earth to explain the γ-ray fluxes. Possible reasons for the few excesses are considered. Our conclusion is important because some of the enigmatic γ -ray 'sources' are identified; furthermore, γ -ray data can be coupled with knowledge about the distribution of gas in the Galaxy to throw light on the problem 'where do cosmic rays come from?'.

y rays are produced when cosmic ray electrons, protons and heavier nuclei collide with atomic nuclei in the interstellar medium (ISM). Insofar as the ISM is not uniformly distributed but contains regions ('clouds') of rather high gas density the γ -ray sky is correspondingly uneven. Of particular interest are those clouds in which the gas, largely molecular hydrogen, is so massive that an excess γ -ray flux can be seen.

Ideally, such clouds could be used to map the distribution of cosmic rays (CR) in the Galaxy, if certain conditions were met: the clouds were of accurately known mass, those clouds selected were 'cosmic ray inert' (that is, generated γ rays only through the interactions of ambient CR and did not contain significant sources of cosmic ray particles) and if the corresponding y-ray fluxes could be accurately measured. If then clouds which were not 'CR inert' were considered, information could be gained about y-ray emission from specific sources and also about particular particle acceleration mechanisms.

Clearly, none of these provisos are met to anywhere near the extent necessary for an accurate analysis but an attempt is desirable because of previous conflicting results (for example, for the cloud associated with ρ -Ophiuci; see ref. 1). A serious objection to previous studies was that the γ -ray sources were taken as the starting point; here we start more rigorously with a set of molecular clouds and then search the γ-ray data for excesses (or deficits) of flux. Hopefully if a large enough sample is taken and the uncertainties in mass and γ -flux are random then the average behaviour will be correct. Unfortunately, there are too few clouds for which data are available to select 'CR inert' clouds. Instead, we must take all clouds for which reasonable mass and distance estimates have been made. The expected γ -ray flux from a cloud of mass M at distance d is estimated from the relation $\Gamma_{\gamma, exp} = (q/4\pi)(M/d^2)$ where q is the emissivity appropriate to the cosmic ray intensity near the Earth (given by Issa et al.) and to compare this with the observed y-ray flux. $\Gamma_{\gamma, {
m obs}}$. Clearly $\Gamma_{\gamma, {
m obs}}/\Gamma_{\gamma, {
m exp}}=I_{
m cloud}/I_0$ where $I_{
m cloud}$ and I_0 are the cosmic ray intensities in the cloud and near the Earth, respectively.

The questions to be asked are: (1) Is the average cosmic ray intensity in the whole sample of local molecular clouds significantly higher than the intensity near the Earth, I_0 ? (Is the average enhancement factor, $F = I_{cloud}/I_0$, greater than unity?) (2) If there is evidence for F > 1 in some clouds and not in others, do they correlate with any known astronomical parameter, such as number of flare-stars, or OB-association?

There is no homogeneous catalogue of masses of molecular clouds determined by the use of one, generally accepted, technique. However, a series of observations by Blitz² give data on seven cloud complexes and these form over half the clouds examined here. The technique was to measure the column density of ¹²CO and ¹³CO lines and convert to H₂ density using the technique described by Blitz and Shu³ and elsewhere (which uses the ratio of $N(H_2)/N(^{13}CO) = 5 \times 10^5$ of Dickman⁴). Important points are the necessity for an upward correction for the gas associated with each cloud which has too low a density to be recorded directly (usually in the 'halo' around the cloud), and for the effect of channel dilution and non-linearity. Furthermore, the possibility of non-thermodynamic equilibrium in local high density regions is important. Blitz favours upward corrections of between 2 and 3. Here we usually adopt a factor 2 to give our estimated upper limit to the mass (the 'Blitz factor') and take the uncorrected mass as a lower limit. Figure 1 gives the location of the selected clouds and Table 1 the estimated masses and distances.

The local thermodynamic equilibrium (LTE) masses are those given by Blitz. Allowance has been made for excesses of atomic hydrogen and ionized gas as well as molecular hydrogen where data are available. Also given are the approximate areas included in our analysis of the clouds and some astronomical information.

Table 1 Estimated masses and distance	s o	of selecte	d clouds
---------------------------------------	-----	------------	----------

Object	Distance (pc)	LTE mass (M _☉)	Mass range (M_{\odot})	Area (deg ²)	Comments	Ref.
Cas OB6	2,000	1×10^5	$1-2\times10^5$	4	W3 & W3N, well known H ₂ regions, best known examples of OB star formation. Strong ionization fronts	
Mon OB1	800	1×10^5	$1-2 \times 10^{5}$	8	Much recent star formation: T-Tauri	2
Mon OB2	1,600	1×10^5 (1 × 10 ⁵ for H ₂	$3-5\times10^5$	4	Rich grouping of early type stars: O stars	2
C.M. OD1	1,100	2×10^{5} for H 1×10^{5}		4	OB and R associations	2
C Ma OB1 Orion OB1	450	2×10^{5}	$2-4 \times 10^{5}$	20	Many flare stars; T-Tauri common; rich in O-associations	2 2
Per OB2	350	4×10^4	$4-8\times10^{4}$	24	Some star formation, T-Tauri and O-type	2
Cygnus	1.700	7×10^{5}	$7-21 \times 10^{5}$	12	Active star formation—OB associations	2
Gum	400	1.2×10^5	$0.7-3\times10^5$	400	Argument about origin of this nebula; considerable ionized gas from supergiants plus stellar winds	28, 29
Cor Aust	150	6.9×10^3	$0.7 - 1.4 \times 10^4$	8	Contains young stellar objects but efficiency of star forma- tion is very low	15, 30
Taurus	140	1.7×10^4	$1.5 - 3 \times 10^4$	100	T-Tauri stars distributed throughout the cloud	6, 7
M17	2,300	$>3\times10^5$	$3-10\times10^{5}$	4	Cluster of O stars has formed at the edge of the molecular cloud	9
Car Neb	2,700		$1.5-3\times10^5\dagger$	5	An unusual object. Star in nebula is one of most luminous in Galaxy. Flared during last century	31
ρ-Oph	160	_	$4.5 - 9 \times 10^3 \dagger$	16	Cloud very dense; comparatively inert but some star formation	32, 33

[†] See text.

There is much argument about the origin of the Gum nebula but agreement that there is considerable ionized gas. In view of the proximity of the Vela pulsar and its spillover (in γ rays) we take only the region $b < -6^{\circ}$. We estimate that $\sim 60\%$ of the gas is in this region (following the H α photograph of Sivan⁵, which suggests that there is more material below the galactic plane than above). The range of masses indicated, which refers to the restricted region, endeavours to bracket the quoted values.

Corona Australis is a useful cloud in that it mirrors ρ -Oph in position and would be expected to have the same cosmic ray intensity in it. Densities in the cores of the sub-clouds are very high. The Blitz factor of 2 possible enhancement in mass has been used but the mass quoted is probably an underestimate.

Taurus 'may be the nearest major aggregate of dust and gas in which star formation is in progress'⁶. It has many T Tauri stars spread throughout the complex. A mass of $1.1 \times 10^4 M_{\odot}$ (within the 0.2 K contour) is quoted by Baud and Wouterloot' for a distance of 113 pc, from observations of OH. For our adopted distance of 140 pc (ref. 6) the corresponding mass is $1.7 \times 10^4 M_{\odot}$ (this is probably an underestimate by ~25% because all the cloud was not surveyed). Another estimate is $2 \times 10^4 M_{\odot}$ using recent ¹²CO data of G. P. Baran (personal communication) for the Taurus and surrounding regions calibrated with the LTE mass obtained by Blitz for the nearby Per OB2 cloud. Bearing in mind the 'Blitz factor' we adopt $1.5-3 \times 10^4 M_{\odot}$ as the likely range for the total mass.

M17 is a bright H II region located on the edge of a large molecular cloud complex which 'may be one of the most massive objects in the Galaxy'⁸. Elmegreen *et al.*⁹ quote a lower limit to the mass of $3.2 \times 10^5 M_{\odot}$, and Elmegreen and Lada⁸ suggest $10^6 M_{\odot}$ for the whole complex. Thus, $3-10 \times 10^5 M_{\odot}$ seems likely.

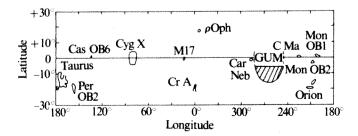

Fig. 1 Positions and approximate shapes of the molecular cloud complexes.

The star associated with the Carina Nebula (η Carinae) is the most luminous in the Galaxy in the IR ($L \sim 6 \times 10^6 L_{\odot}$). There is strong evidence for an ionization front generated by stars in the Trumpler 14 and 16 clusters, and associated compressed H and H₂ regions¹⁰. The mass is very uncertain because of the lack of CO observations. The estimate of gas in ionized form comes from Dickel's analysis: $1-2\times10^5 M_{\odot}$. In view of the inevitable contribution from H and H₂ and the Blitz factor we adopt $1.5-3\times10^5 M_{\odot}$ as the likely range.

We previously favoured ρ -Ophiuchi because of its being comparatively inactive: astronomically^{1,11} there are no associated O-stars or bright H II regions ¹² although there are several small compact H II regions ¹³. There is uncertainty in the mass (see refs 11, 14 for conflicting estimates). Here we consider the following: Myers et al. ¹² quote $1.8 \times 10^3 M_{\odot}$ (assuming LTE) out to a radial distance of 2.1 pc for H + H₂; Grasdalen et al. ¹³ give $4 \times 10^3 M_{\odot}$ for a somewhat smaller region, Vrba ¹⁵ quotes $6.1 \times 10^3 M_{\odot}$ in total. Our previous estimate overall from CO data was $\sim 9 \times 10^3 M_{\odot}$, inclusive of ionized gas (Baart et al. ¹⁶ find that such gas is common) but our analysis of stellar extinction led to values of about half this. Thus, we adopt $4.5-9 \times 10^3 M_{\odot}$ in the present case.

The γ -ray results will now be considered. The data come from the SAS 2 and COS B experiments. The SAS 2 data comprise the comprehensive tables of Fichtel $et~al.^{17}$ for the two energy ranges 35–100 MeV and $E_{\gamma} > 100$ MeV, and the contours for l 150°–240° and |b| < 25° given by Thompson $et~al.^{18}$. COS B results have not yet been given in tabular form and we have used other sources: the contours for $E_{\gamma} > 70$ MeV of Wills $et~al.^{19}$ which relate to all longitudes and largely to |b| < 15°, the cut along b=0° given by the same author and sections for 70–150 MeV, |b| < 7°; 150–300 MeV, |b| < 5° and 300–5,000 MeV, |b| < 4° given by Mayer-Hasselwander $et~al.^{20}$. The 2CG catalogue of COS B sources of Hermsen²¹ has also been used.

For each cloud we delineate an area surrounding it some $3-4^{\circ}$ wider than the cloud (the exact area depending on γ -ray energy and the source of data: tabulated fluxes, contours and flux versus longitude plots for fixed latitude bins) and compare the integrated γ -ray flux in this region with its surroundings, usually by way of adjacent longitude bins for the same latitude range. The adopted flux is the flux in the region less the average of its surroundings. The greater coverage than the 'source' area is to allow for at least some of the γ rays which fall outside the area because of errors of γ -ray direction (the 'point spread function'); a correction is applied for the effect of residual loss, that is, net loss even out of the enlarged area. The excess flux which can be

^{*} This value is from the analysis of Protheroe et al. 34 using column densities but converting to $q/4\pi = 2.2 \times 10^{-26} \text{ s}^{-1} \text{ sr}^{-1}$ as adopted here.

attributed to the cloud is estimated using the above sources of data. Where the flux is negative, upper limits at the 1σ level are derived.

This cannot be an accurate procedure as there are many problems associated with inhomogeneous backgrounds and poor statistics; however, it seems to be objective and we can see no reason for the eventual average (or better, the median) value of the flux enhancement factor, F, being either underestimated or overestimated.

To improve accuracy, the data are combined to give an estimate of the flux above one energy level: $100 \, \text{MeV}$. To this end, the SAS 2 fluxes for $35:100 \, \text{MeV}$ are multiplied by 0.68 to give the equivalent flux above $100 \, \text{MeV}$.

Table 2 gives the observed and our estimated γ -ray fluxes and the enhancement factor, F. The 2CG notation refers to the COS B source catalogue of Hermsen²¹ and these fluxes are taken where the 'sources' are in such positions as to be not inconsistent with the clouds. Positive identification is not possible, however, and there are doubts in some cases. The COS B flux value for Orion comes from Caraveo et al.²² which relates to $E_{\gamma} > 70 \text{ MeV}$ ($\approx 2 \times 10^{-6} \text{ cm}^{-2} \text{ s}^{-1}$); conversion by the spectral shape factor yields $\approx 1.4 \times 10^{-6} \text{ cm}^{-2} \text{ s}^{-1}$ above 100 MeV. This value is close to the $1.0 \times 10^{-6} \text{ cm}^{-2} \text{ s}^{-1}$ derived from analysis of SAS 2 data¹¹. (Note that Caraveo et al. derive $F \approx 1$ by adopting a mass of $1.2 \times 10^{5} M_{\odot}$, derived from Galaxy count studies.) No value is given for the flux for those regions where no data have been reported (or at least there are no data over a wide enough $\Delta l \times \Delta b$ range to allow flux estimates to be made).

Figure 2 shows the values of F listed in Table 2 plotted against the distance from the Earth, d. Ideally F should be plotted against distance from the axis of the nearest spiral arm (in an effort to search for an arm-interarm contrast in cosmic ray intensity) but the positions of the axes are not sufficiently well known. Although not necessarily expecting a dependence of F on d over the range indicated we do expect a loss of reliability at large d because of the possibility of confusion from other clouds and this will be particularly severe when looking roughly along the axis of a spiral arm (specifically for Car Neb and, to a lesser extent, Cygnus). In fact, the 2CG COS B source catalogue lists 2CG288-00 (the Car Neb source) and 2CG284-00 nearby as 'could be an extended feature'.

Taking the data in Fig. 2, the average value of F is ~ 1.3 , weighting according to the errors indicated. Although this estimate is not very precise in view of there being errors in γ -ray

flux, which have not been included, the extra errors should be symmetrical and the estimate should not be too far out. It seems likely, then, that most of the clouds do not have much enhancement $(F \le 2)$ of cosmic ray intensity within them. In this sense the results are consistent with a previous analysis²³ in

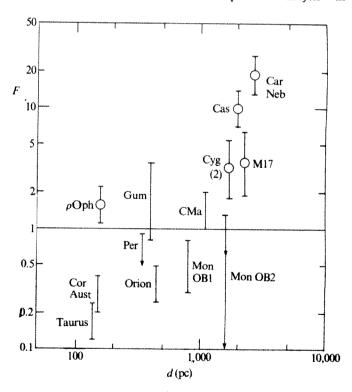

Fig. 2 F-values for the molecular clouds indicated. The ranges shown come from uncertainty in cloud mass; no uncertainty in γ -ray flux has been allowed for. The flux errors are expected to be roughly symmetrical so that the best-estimate F-values will not change. The abscissa is the distance from the Earth. The circles on some of the error bars indicate clouds which may be identified with γ -ray sources in the 2CG catalogue; the 2CG γ -ray fluxes have been adopted in the calculations (the (2) against Cygnus denotes two COS B sources). The astronomical data of Table 1 are probably best for Orion OB1, Per OB2 and Mon OB2 (J. Meaburn, personal communication).

which it is claimed that over half of the 2CG sources could be explained as being due to CRI molecular clouds, the analysis being made on a statistical basis.

Despite the large uncertainties there are some features which are worthy of further attention.

(1) The cloud complexes within 1 kpc of the Earth mainly have F < 1. Some of these have many T-Tauri stars and this indicates that the stellar winds from T-Tauri stars are not the seat of much cosmic ray acceleration or, at least, if they do accelerate particles then they escape rapidly from the environment of the stars (the likelihood of CR acceleration by stellar winds was first pointed out by Cassé and Paul²⁴). It is possible, but not certain, that some of the low values of F relate to the position of the clouds—they may be preferentially in interarm regions. Beyond 1 kpc (where T-Tauri stars cannot be identified) F-values are generally higher and there seem to be frequent OB-associations. The significance of this is not clear because of selection phenomena; the relevance of OB-associations to y-ray sources has already been discussed by Montmerle25 who required nearby supernovae ('SNOB'S') to augment I_{cloud} . We do not feel much increase in flux is needed.

(2) The only clouds which seem to need F-values significantly greater than unity are Car Neb and Cas OB6, the differences from unity for the others can be attributed in part to errors of γ-ray flux, and of cloud mass and to the likelihood of small variations of F from place to place on a large scale.

The excess in Car Neb may be genuine, with particle acceleration occurring in a manner such as described by Montmerle26. However, several features need stressing. The first concerns the fact that the direction of Car Neb is congested in the sense that it is along a spiral arm and other clouds may also be contributing within the angular resolution of the instrument. The mass of cloud needed (at the distance of Car Neb) is $=3\times10^6 M_{\odot}$; although large, this is not an impossibly large mass for a single giant molecular cloud. The inclusion of other clouds would relax the mass requirement considerably. Also the identification of 2CG288-00 with Car Neb may be erroneous. The source could be, for example, a pulsar in this direction; pulsars do emit γ rays.

There is the same possibility of mis-identification with Cas OB6. Coincidence of more than one cloud is unlikely, however, because the direction is not along an arm. What is interesting is the fact that Cas OB6 is in a well developed arm—the Perseus arm-and the possibility of some general CR intensity enhancement arises.

Although all the data—both γ-ray and astronomical—are poor such evidence as there is does not call for much CR enhancement in most of the molecular clouds within 1 or 2 kpc of the Earth $(\langle F \rangle = 1.3)$ for all the clouds in Fig. 2 and even nearer unity for d < 2 kpc). Unidentified molecular clouds irradiated by CR and situated beyond 2 kpc are likely contenders for the so-called y-ray sources and, indeed, there are indications²³ that ~60% of the COS B sources can be explained in this way.

Thus the studies of the large scale distribution of γ -ray flux, in which unresolved discrete sources have been neglected and it has been concluded that there are large scale cosmic ray gradients in the Galaxy, should be valid (see, for example, ref.

We do not suggest that the sources of some of the low energy cosmic rays are not in molecular clouds. They could well be, but diffusion will probably distribute the particles so rapidly that those interacting in a particular cloud are mainly from the general ambient cosmic radiation.

We thank Dr L. Blitz for the copy of his thesis and Dr A. W. Strong for helpful comments. Dr J. Meaburn and Dr S. M. Scarrott suggested improvements to the manuscript.

Collisional amplification of density fluctuations in Saturn's rings

J. Lukkari

Department of Astronomy, University of Oulu, Oulu, Finland

The encounter of Voyager 1 with Saturn in November 1980 revealed the ringlet structure of its rings. As the theoretical examination of the collisional evolution of keplerian systems1,2 had predicted such a structure in dense matter as a consequence of amplified fluctuations in density, some new computer simulations have now been carried out to check this effect. These simulations actually led to a strong, irreversible growth in the density maximum.

Let a keplerian system consist of frictionless, spherical and identical particles revolving around the central body along elliptic orbits and having the radius σ . Let a denote the semimajor axis, ε the eccentricity, i the inclination, γ Newton's constant and m the mass of the central body. The local value of optical thickness is τ .

Solid materials have a restitution coefficient, α , which decreases with the velocity of impact, v. If α_0 denotes the particular value of α which corresponds to the root-meansquare velocity of impacts, the system adjusts itself to a state in which2

$$\frac{9\pi^2(19\alpha_0 - 13)}{64(1 - \alpha_0^2)(3 - \alpha_0)^3} = g^2\tau^2, \qquad \alpha_0 = \alpha(\sqrt{\overline{v^2}})$$
 (1)

The weight function g is a correction for the finite volume of the particles; if the space density is low, we have g = 1. As the space density depends on the geometric thickness of the system, its optical thickness is not restricted by the value of g. If equation (1) is valid, the radial component of the two-dimensional flux vector which represents the transport of particles on the equatorial plane of the system can be calculated from

$$F^{a} = -\frac{8}{9\pi^{2}\sigma^{2}\sqrt{\gamma ma}}\frac{\partial}{\partial a}\left[g\tau^{2}a^{2}T(1-\alpha)\sqrt{(1+\alpha)(3-\alpha)}\right]$$
 (2)

The temperature-like quantity T is approximately equal to $3\overline{v^2}/4$. According to equation (1), $\sqrt{v^2}$ is a decreasing function of

the optical thickness, as has also been found by Goldreich and Tremaine³. If τ is high enough, this effect produces a decrease in the function inside the square brackets in equation (2). For example, if $\alpha = (1+v/v_0)^{-1}$ ($v_0 = \text{constant}$) and g = 1, this function has its largest value at $\tau = 0.75$. If τ exceeds it, the flux is directed to the density maximum. If τ is small, the same function increases with τ and the flux is directed away from the maximum density. In particular, as $\tau \to 0$ at the boundaries of the system, these expand with a macroscopic velocity $\pi \sigma^2 F^a / \tau \sim -\partial \tau / \partial a$. As a whole, the system therefore expands. This agrees with Brahic's conclusion. As Brahic derives the expansion from the conservation of the total angular momentum of the whole system and from a simultaneous decrease in its total energy, his result cannot be generalized for parts of a system. Their angular momentum may increase or decrease according to the interaction with adjacent regions. A local contraction of matter is therefore possible.

In the present report we are not studying the general expansion, but are testing the reality of the amplification of fluctuations which is predicted by equation (2) at high values of τ . Because Saturn's rings exist, the time scale of the expansion must be long or some mechanism must prevent it. The formation of ringlets has a shorter time scale. Once the fluctuations have begun to grow, the gradient in equation (2) becomes progressively steeper and the flux increases until the finite size of particles stops the process.

Previous simulations⁵ with a constant coefficient of restitution indicate that the validity of theoretical predictions with g = 1 is restricted by the condition $\sqrt{i^2} \gg 4\sigma/a$. On the other hand, in a ring-shaped system of radial width w, the gradients in density and in the distribution functions are too high unless $w/2 \gg a\sqrt{\varepsilon^2}$, $a\sqrt{i^2}$. This follows from the limits of validity for theoretical expressions^{2,5}. As $\sqrt{i^2/\overline{\epsilon}^2} = 2/3$ in the equilibrium state⁵, we can also write both conditions in the form $w \gg 2a\sqrt{\overline{\epsilon}^2} \gg 12\sigma$. If the sign » is interpreted to mean the ratio 5:1, the above condition can be written $w \ge 300\sigma$. The number of particles in a ring of optical thickness τ is $2aw\tau/\sigma^2$. If $\tau > 0.75$ as in the abovementioned numerical example, and if $\sigma/a = 0.001$, a system of 450,000 particles is needed to satisfy the condition $w \ge 300\sigma$. The large number of particles prevents the direct simulation of dense matter (Saturn's rings). Because the dependence between τ and α is of a statistical nature, one cannot even use a Monte Carlo method, which only increases the number of particles but does not change their statistics. We must therefore use an indirect method.

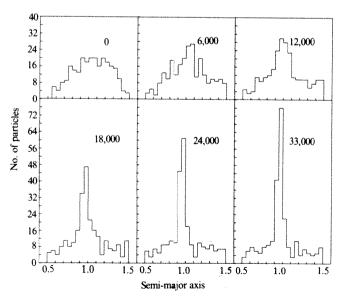

Fig. 1 Radial distribution of particles during one simulation. The number of collisions is given beside each histogram. The corresponding times are 0, 132,000, 247,000, 335,000, 403,000 and 484,000 in units in which $\sigma = 0.001$ and $\gamma m = 1$.

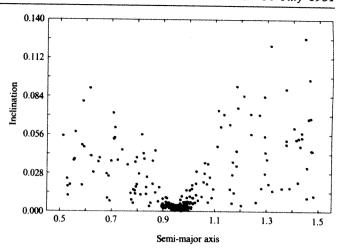

Fig. 2 Inclinations of the orbits as a function of semi-major axis after 30,000 collisions.

In rarefied matter, equation (1) gives the result $\alpha_0 = 13/19$, which has also been confirmed by a computer simulation. Applying this result we can artificially force a rarefied system to behave in the same manner as a dense one. For this purpose it is sufficient to use a coefficient of restitution which depends on both v and τ and produces the result $d\sqrt{v^2}/d\tau < 0$, when the system adjusts itself to $\alpha_0 = 13/19$. This corresponds to equation (1). The function $\alpha(\tau, v)$ can be so chosen that the simulation produces the same flux as equation (2) (but not with the same value of v^2) if the elastic properties of matter are specified. Because we lack this information we can choose $\alpha(\tau, v)$ freely.

In our simulations the restitution coefficient was

$$\alpha = \frac{1}{1 + k(\tau^3 + \tau_0^3)v} \qquad k, \tau_0 = \text{constant}$$
 (3)

In units $\gamma m = 1$, the constants of equation (3) are $k = 1.91 \times 10^{12}$ and $\tau_0 = 7.52 \times 10^{-5}$. The number of particles in zones of width 0.1 was used to calculate the local values of τ . The number of particles is 250 and their radius is 0.001. The initial distribution of τ is proportional to (1.5-a)(a-0.5) while the initial values of $\sqrt{\overline{\varepsilon^2}}$ and $\sqrt{\overline{i^2}}$ are 0.049 and 0.032, respectively. As the number of particles is restricted, we cannot simulate a sequence of adjacent density fluctuations. It is therefore necessary to pick up just one condensation and to follow its evolution. To simulate the pressure of adjacent regions, the particles which were outside the initial zone 0.5 < a < 1.5 after a collision were brought back into it. The percentage of such impacts was usually <1%. A slow expansion of this zone would not change the result. The same process can also be interpreted as replacing the unknown mechanism which prevents the general expansion of boundaries in saturnian rings. If the post-collisional semi-major axis was <0.5, it was replaced by 1-a. If it was >1.5, it was replaced by 3-a. This has no primary effect on the development of the central spike, because the maximum change of semimajor axis in a collision is usually not larger than 2ea. Figure 1 shows the evolution in the radial distribution of the particles in one of the simulations. The increase in density is clearly seen after 6,000 collisions and it continued when the simulation was stopped after 33,000 collisions. Contraction continues although the inclination was at its densest part $\sim 2\sigma/a$, which has previously led to an increasing dispersion of the system⁵. The system thus achieved a state in which α was not able to reach its quasi-equilibrium value 13/19 but remained smaller.

Figure 2 represents the distribution of inclinations as a function of the semi-major axis after 30,000 collisions. As can be seen the large inclinations in rarefied matter between the ringlets may well cause the observed thickness of Saturn's rings, whereas the thickness of the ringlets is much smaller.

Extremely rarefied matter outside Saturn's rings or selfgravitation or some external perturbation is needed to prevent the extreme borders of the whole sequence of ringlets from dispersing into space. If this is assumed, then the simulations show in accordance with the theory 1.2 that an initially almost homogeneous ring of dense matter is spontaneously divided into ringlets.

The ice layer in Uranus and Neptune—diamonds in the sky?

Marvin Ross

University of California, Lawrence Livermore National Laboratory, Livermore, California 94550, USA

Many of the current models of Uranus and Neptune postulate a three-layer structure, consisting of an inner rocky core, a middle 'ice' layer of fluid, H2O, CH4, NH3 and an outer hydrogenhelium layer of solar composition1. The estimated pressures and temperatures of the ice layer ranges from about 6 Mbar and 7.000 K at the inner core-ice boundary, to ~0.2 Mbar and 2,200 K at the outer ice/hydrogen-helium boundary. I point out here that shockwave experiments on these liquids²⁻⁵, as well as theoretical studies⁵⁻⁷, imply that the H₂O and NH₃ in the ice layer are almost totally ionized and the CH4 has been pyrolysed to carbon, possibly in the metallic or diamond form

In recent years shock-wave experiments have been carried out on all of the fluid constituents of the outer planets except helium. In a shock-wave experiment, the change in pressure, density, and energy, on compression are measured, but the temperature must be computed from the equation of state. A series of experiments starting from the same initial conditions (that is, the normal liquid) and spanning a range of final pressures and densities is referred to as a Hugoniot curve. Figure 1, in comparing some of these data for the 'ices' with an isentrope calculated for Uranus (Neptune is very similar) demonstrates the significance of the data to theoretical modelling studies of these planets. For methane the experimental data, only some of which is shown, consists of a principal Hugoniot up to 0.45 Mbar, plus one data point reflected from 0.23 to

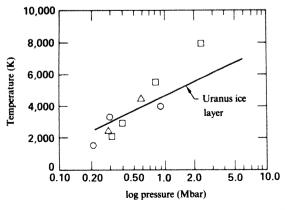

Fig. 1 Plot of some of the experimental shock-wave data for water (\Box) , ammonia (\triangle) and methane (\bigcirc) in the range of temperatures and pressures believed to exist in the Uranus (and Neptune) ice layer.

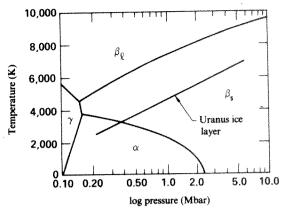

Fig. 2 The Uranus (and Neptune) ice layer (straight line) compared with pressure and temperatures for the diamond phase diagram of Grover⁸. α , Diamond; γ , graphite; β_s , metallic solid; β_1 , metallic liquid. Van Vechten's phase diagram predicts that in the region of the isentrope, above ~0.4 Mbar, carbon will be a liquid metal.

0.91 Mbar. It has recently been shown that an apparent deviation from predicted molecular behaviour could be explained by the tendency for CH₄ to dissociate in these conditions⁶. These conclusions were based on chemical equilibria calculations which predicted that above 0.20 Mbar and 2,000 K, methane is converted into elemental carbon and molecular hydrogen, Recent theoretical calculations on Hugoniots of many hydrocarbons indicate that shock heating induces breaking of the C-H bonds, and the compression encourages condensation of the dissociated carbon atoms into a residue7. If we assume that the hydrocarbons have been completely converted into a mixture of condensed carbon and molecular hydrogen, we can use known equations of state for each of these materials to compute highdensity Hugoniots that are in excellent agreement with the experimental hydrocarbon data. The results of similar calculations for molecular methane⁶ also agree with the experimental data suggesting that the final product is also hydrogen and a carbon residue.

The Uranus isentrope is shown again in Fig. 2, this time plotted with the recently proposed carbon phase diagrams of Grover⁸. Van Vechten⁹ had previously proposed a carbon phase diagram. Although they differ somewhat in detail above 3,000 K and 0.4 Mbar, they do agree in predicting that below these conditions carbon will exist in the well-known 4-coordinated diamond form. Above these conditions Grover predicts that carbon along the planetary isentrope will be in a metallic solid phase whereas Van Vechten predicts a liquid metallic phase. In Van Vechten's theory the close-packed metal becomes liquid at temperatures well below those of the planetary ice layer. Currently, hydrogen is believed to become a metal somewhere between 2.0 and 5.0 Mbar. Consequently, over much of the higher pressure range of the isentrope the hydrogen freed from the molecular methane will also be metallic and may form a metallic carbon hydrogen mixture.

As indicated in Fig. 1, shock-wave data on water and ammonia, including electrical conductivities, have been measured over part of the Uranus (Neptune) pressuretemperature range. The electrical conductivity data shows that above 0.2 Mbar and about 2,000 K the conductivities become constant at ~20-30 S cm⁻³, as if the processes leading to ionization have become saturated. Water has apparently become fully ionized³. For ammonia similar results have been observed³. Consequently we must conclude that in the Uranus and Neptune ice layer H₂O and NH₃ are not molecular but ionic, and that the carbon in methane has been converted to a diamond or metallic phase with molecular or metallic hydrogen. Shock-wave data on diamond and graphite shows that the carbon condensate at a few megabars will be denser than NH₃ or H₂O and, unless it is highly soluble in the fluids, may separate out and sink below to form a denser layer.

The electrical properties of these ices are of great interest because they can lead to an explanation or a prediction of a magnetic field. The motion of charged particles trapped in such magnetic fields generates radio waves. There is one report of possible radio signals from Uranus, but there have been no similar reports from Neptune 10. The significance of a conducting layer of carbon may be very great because it is estimated that the mass of available carbon in Uranus and Neptune is 17% of the total planetary mass1.

A refined estimate of the fine structure constant

John Ellis & D. V. Nanopoulos

CERN, CH 1211 Geneva 23, Switzerland

Quantum electrodynamics (QED) is an immensely powerful theory whose validity extends over distance scales from 10^{-16} cm to light years. But it is unsatisfactory for many reasons, not least of which is the arbitrariness of the electromagnetic coupling strength, the fine structure constant α , and the incomprehensible commensurability of the electric charges of different particles. When extending QED to distances smaller than 10^{-16} is common to combine it first with the weak interactions 1-3 and subsequently with the strong interactions into a grand unified theory (GUT) of all elementary particle interactions^{4,5}. The incorporation of QED and the other fundamental interactions into a GUT is only possible if these interactions and the particles experiencing them satisfy some non-trivial constraints⁶. It is well-known that the incorporation of QED into a simple unifying group imposes charge quantization 4,5. Stability of baryons in GUTs requires the grand unification energy scale m_x to be \geq 10¹⁴ GeV. Couplings in renormalizable field theories such as QED evolve logarithmically with energy, and for the effective α to be less than unity-necessary if the GUT is to make sensethen >1/25 (ref. 7). We point out here that within the same standard set of grand unifying assumptions used previously, a much more refined estimate of the fine structure constant is possible: $1/120 \ge \alpha \ge 1/170$. We use only the general observations⁶ that light fermions can be grouped into 'families' or 'generations' of 15 helicity states, that the strong interactions become strong of a scale of the order of 1 GeV, and that any grand unification energy scale must lie between 1014 (for baryons to be stable enough) and 10¹⁹ GeV (the energy at which gravity becomes of unit strength). We know of no other theoretical framework⁸ for particle interactions which can provide such convincing and restrictive constraints on α , and we find it hard to believe that the experimental value of $\alpha = 1/137$ is a coincidence.

We now recall some basic features of the GUTs before deriving our upper and lower limits of α (for more complete descriptions see refs 6, 7, 9). The strong interactions are described by a non-Abelian SU(3) gauge group, while the weak and electromagnetic interactions are described by a theory

based on the group $SU(2) \times U(1)$. The ratio of the gauge coupling constants g_2 and g_1 in this theory is arbitrary, and is parametrized by $\sin^2 \theta_W$, and the fine structure constant $\alpha = \alpha_2$ $\sin^2 \theta_{\rm W}$ where $\alpha_2 = g_2^2/4\pi$. The strong, weak and electromagnetic interactions act on fundamental fermions, the quarks and leptons, which seem to be arranged^{4,5} in sets of 15 helicity states called 'families' or 'generations'. GUTs combine the different SU(3), SU(2) and U(1) gauge interactions into a simple group G, and assign the fermions to 15 dimensional representations of G. It has been emphasized⁶ that it is not trivial that the observed fermions fall into representations of 'low energy' symmetries which can be grand unified.

Grand unification introduces new gauge interactions between the fermions which violate baryon and lepton number conservation. They are mediated by heavy gauge bosons of masses m_x heavier than 1014 GeV if protons and bound nucleons are not to have lifetimes shorter than the present experimental lower limit¹⁰ of 10³⁰ yr. In their present formulations, GUTs do not include gravitation^{11,12}. As quantum gravity effects (such as one-graviton exchange) become important at energies comparable with the Planck mass of 1.2×10^{19} GeV, it follows that the grand unification mass scale must be $<10^{19}$ GeV if the GUT concept is to make sense.

The grand unification mass scale can be estimated¹³ using the renormalization group 14,15, the idea being that while the SU(3), SU(2) and U(1) coupling constants are equal above this scale, below it they have different logarithmic dependences on the effective energy scale at which they are measured. This is how13 the SU(3) interactions can become strong at energies of the order of 1 GeV, while the $SU(2) \times U(1)$ weak interactions can be weak at low energies. For the GUT philosophy to be viable, the 'low-energy' weak interactions must be neither too strong-in which case grand unification would occur at too low a mass scale and baryons would decay too fast—nor too weak—in which case grand unification would not occur before the Planck mass and it would have been wrong not to have included gravity.

The fine structure constant $\alpha = \alpha_2 \sin^2 \theta_W$, where $\sin^2 \theta_W$ is determined by GUT to be 3/8 in the symmetry limit above the grand unification scale^{4,5,13}. (The variation of $\sin^2 \theta_W$ below this scale has been computed^{13,16,17}, and the value of 0.21–0.22 found at low energies lies within 1 s.d. of the present experimental value (I. Liede and M. Roos, personal communication).) Knowing the symmetry value of $\sin^2 \theta_w$ we can translate the 'grand unifiability' restriction on the weakness of the weak interactions into upper and lower limits on α itself. In the leading order approximation, the renormalization group equations at energy scales Q between 100 GeV ($\approx m_{W\pm}$, m_{Z0}) and the grand unification scale m_X tell us that

$$\frac{1}{\alpha(Q)} \approx \frac{11}{\pi} \ln \left(m_{\rm X}/Q \right) + \frac{8}{3} \frac{1}{\alpha_3(Q)} \tag{1}$$

if we only include GUT representations of fermions and gauge bosons. From renormalization, if $\alpha_3(Q)$ is of the order of 1 on a typical hadronic energy scale then it should be of the order of 0.1-0.2 when $Q \sim 100$ GeV (refs 18-21). There is also a change in the effective $\alpha(Q)$ between its value at the Thompson limit Q = 0, which is where we define and measure α , and its value at $Q \approx 100 \,\text{GeV}$:

$$\frac{1}{\alpha} \approx \frac{1}{\alpha (100 \,\text{GeV})} + 9 \tag{2}$$

If we use these low energy renormalizations of $\alpha_3(Q)$ and $\alpha(Q)$ and require 10^{14} GeV $< m_X < 10^{19}$ GeV in equation (1) we find $1/119 < \alpha < 1/174$ which we have rounded off to the values quoted earlier. Including a possible light Higgs boson into the leading order renormalization group equations changes these bounds by $\sim 1\%$.

Any theorist working on grand unification would have known

$$\frac{m_{\rm X}}{\Lambda_{\rm QCD}} = \exp\left\{\frac{0(1)}{\alpha} + 0(1) \times \ln \alpha + 0(1) \times \alpha^0 + \ldots\right\}$$
(3)

and put in the known value of α to determine m_X in minimal GUTs within a factor of 10 or less²². However, to our knowledge no-one has inverted the procedure and pointed out how tightly constrained a grand unfiable α must be. Indeed the previous upper limit on α from GUTs was much weaker than the present one. The most precise estimates²² of m_X have gone beyond our leading order formula (1) to include all the lnc and oterms of equation (3). As we intend to convey a qualitative message, we will not repeat all those calculations here. However, we emphasize that they should enable one to make an even more refined estimate of α if baryon decay is ever observed. This is because the baryon lifetime²² is very sensitive to the value of m_x :

$$\tau_{\text{baryon}} \approx 8 \times 10^{30 \pm 1} \,\text{yr} \times \left(\frac{m_{\text{X}}}{6 \times 10^{14} \,\text{GeV}}\right)^4$$
 (4)

Hence a determination of $\tau_{\rm baryon}$ should enable us to fix $m_{\rm X}$ within a factor of 1.5 or so. This 10-fold improvement in bounding m_X would in turn enable us to estimate α^{-1} an order of magnitude more precisely say to ± 3 . The fact that α lies closer to the upper limit we have established gives us hope that m_X is closer to 10^{14} GeV than to 10^{19} GeV, and more detailed estimates in popular GUTs strongly suggest²² that the baryon lifetime is sufficiently short to be detectable in the forthcoming generation of experiments.

Dynamical symmetry in the quadratic Zeeman effect

C. W. Clark & K. T. Taylor

Science Research Council, Daresbury Laboratory, Daresbury, Warrington WA4 4AD, UK

Zimmerman, Kash and Kleppner¹ have recently posulated the existence of a 'hidden' symmetry in atomic hydrogen in a uniform magnetic field. We have drawn similar conclusions from independent work2. Here, we show that the quasi-constant of the motion in this system can be related in a simple way to the asymptotic form of the quantum mechanical wavefunction. This development is consistent with the broad outline drawn by Fano^{3,4} who has emphasized the role of this particular problem as a member of a large and important class of dynamical systems characterized by the existence of motion along a 'ridge' of a potential surface.

Such motions are intrinsically unstable, because a fall off the ridge into a region of lesser potential is always possible. Nevertheless, it is frequently the case that important observable quantities are determined solely by these unstable motions. This has long been known^{5,6} to be so for the most prominent other member of this class, the system of two electrons escaping simultaneously from the field of an ion, which occurs in problems of electron impact ionization and multiple photoionization of atoms. Thus, a thorough understanding of the quadratic Zeeman effect, necessary in itself for the interpretation of current experiments, may also be relevant to more general questions of atomic dynamics. We draw special attention here to the analogy provided by the problem of two-electron escape, in which competing modes of partial escape

$$e + e + A^{2+} \rightarrow e + (A^{+})^{*}$$

give rise to the Wannier threshold law^{5,6}.

We focus our discussion on the interpretation of Fig. 1, the bottom frame of which shows the oscillator strength for dipole transitions from the ground state of hydrogen to excited states with a single quantum of angular momentum in the direction of the magnetic field. These 'experimental' data were obtained by diagonalizing the hamiltonian within a large basis (\sim 1,500) of sturmian functions, using a set of banded matrix routines developed at the National Physical Laboratory which have been implemented on the CRAY-1 computer at Daresbury. The field strength is 4.7 T. Transitions to these states would result from absorption of light with circular polarization about the axis of the magnetic field. The lowest cluster of lines shown corresponds to the perturbed manifold of hydrogenic states with odd parity and principal quantum number n = 23. As the energy of the final

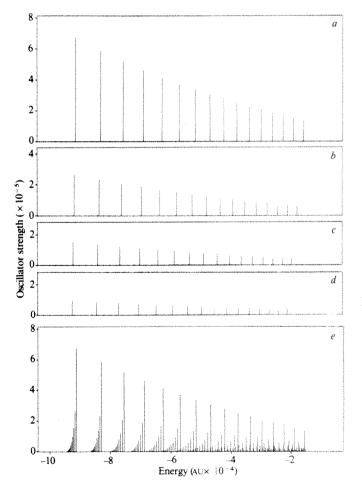

Fig. 1 The oscillator strength for absorption of circularly polarized light by atomic hydrogen in the ground state, for photon energies below the ionization limit. a, The principal series; b-d, second, third and fourth series; e, all lines present in this energy range. The abscissa is the total energy minus the linear Zeeman shift.

state increases the line clusters interpenetrate, with a surprising lack of mutual perturbation among lines of comparable oscillator strength with nearly equal energy. We are thus led to view this spectrum as a superposition of many essentially independent line series. The first four such series, in order of spectroscopic prominence, are drawn out in the upper frames of Fig. 1 (the 16 lowest members of each series only are displayed in these frames). Complementary evidence for this classification scheme can be inferred from the independent work of Zimmerman et al.¹, who have shown the dependence of lower energy levels on magnetic field strength at stronger fields. Their plots exhibit many near crossings of energy levels, which would be forbidden on general grounds⁷ except in the presence of an additional constant of the motion.

Corroborative information is obtained by examining the appropriate solutions to the quantum mechanical equations of motion. The hamiltonian for this system, if the centre-of-mass motion and relativistic effects are disregarded, is the same as that for a hydrogen atom in the absence of a field, with an additional term describing the interaction of the electron with the field. This term contains a part that is linear in the field strength and depends only on the projection of the electron's angular momentum on the field direction; this gives rise to the familiar linear Zeeman effect, which consists of a constant energy shift of all lines in the spectrum of Fig. 1. The remainder of the magnetic interaction is quadratic in the field strength, and results in the Schrödinger equation (in atomic units)

$$\left(-\frac{1}{2}\frac{\partial^2}{\partial r^2} + \frac{\vec{\mathbf{l}}^2}{2r^2} - \frac{1}{r} + \frac{1}{2}\boldsymbol{\beta}^2 r^2 \sin^2\theta\right) \psi = \varepsilon \psi \tag{1}$$

where $\tilde{\mathbf{I}}$ is the electron angular momentum operator, β one-half the magnetic cyclotron frequency, θ the angle between the magnetic field $\vec{B} = B\hat{z}$ and the electron position vector \vec{r} , and ε is the total energy minus the linear Zeeman shift. The last term on the left-hand side of equation (1) is a repulsive potential which assumes its maximum value in the plane z = 0. Because of the very small value of β ($\beta = 10^{-5}$ for a 4.7 T field), this term has a significant effect on the motion only at large distances r, where the potential surface takes the form indicated in Fig. 2. The equipotential surfaces are essentially spherical at small r, and cylindrical at large r. Thus, in photoabsorption the initial state of the electron, being tightly bound to the nucleus, is essentially spherical; the final state, which has significant amplitude at large distances, must eventually conform to the cylindrical geometry of the potential surface there. Understanding this transition between disparate geometries has constituted a major difficulty for the theory. In the problem of double photoionization also, the initial state has a more or less spherical symmetry, and the two electrons are not too strongly correlated. Dynamical analysis shows, however, that the only final state configurations which

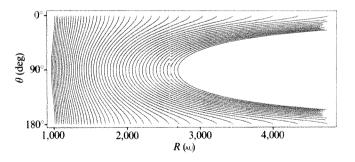

Fig. 2 The equipotential lines for electron motion in the field of a proton and a 4.7 T magnetic field. The ordinate is the angle θ subtended by the position vector and the magnetic field, the abscissa the electron-proton distance, R, in units of Bohr radius. The rightmost equipotential line corresponds to the energy $\varepsilon = 0$; the energy spacing between successive lines is one-fifth of the magnetic cyclotron frequency. A potential ridge is apparent at the angle $\theta = 90^\circ$.

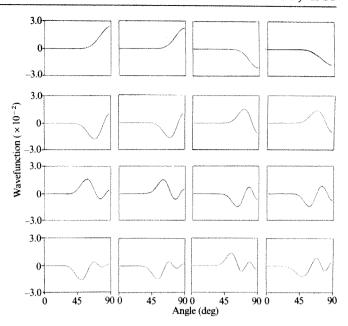

Fig. 3 Wavefunction versus angle along the appropriate turning line for selected states of the first four series. First row: the 1st, 5th, 10th and 16th states of the principal series as indicated in Fig. 1; second and third rows: the corresponding states of the second and third series; fourth row: the 1st, 5th, 10th and 15th states of the fourth series, the 16th state being strongly perturbed. All wavefunctions are symmetric about 90°.

lead to double ionization are those in which the two electrons lie at equal and opposite distances from the ion. Such configurations are unstable and can be considered as located on a ridge of the potential describing the interaction among the three particles of the system. A fall off the ridge results in capture of one of the electrons into a high Rydberg state. In our Zeeman problem the quadratic potential displays a ridge in the plane z=0. We shall show that a large fraction of the oscillator strength is associated with motion of the electron along this ridge, as has been suggested by early semi-classical treatments of the problem. In this case the fall off the ridge leads to escape of the electron along the magnetic field.

We consider first the principal series of Fig. 1, the members of which are shown in the top frame. We have computed accurate wavefunctions for the states of this series using the method indicated above, which has been described in more detail elsewhere². Briefly, each wavefunction is represented by expansion in terms of products of spherical harmonics and sturmian functions, the coefficients of which are determined by the diagonalization of the hamiltonian matrix. In the absence of a magnetic field these states would reduce to hydrogen wavefunctions with angular momentum l=1, and would carry all the oscillator strength. If the effect of the field is regarded as perturbative, which is appropriate for the lowest members, some higher angular momenta are mixed in with a resulting diminution in the oscillator strength. The higher members of this series are not characterized by the predominance of any one value of the angular momentum at small r. If, however, we look at the wavefunction at large r a simple consistent pattern emerges. Figure 3 shows the variation of the wavefunctions for some of these states along their classical turning lines, that is, those lines of Fig. 2 for which the equipotential energy is equal to the energy of the states. The wavefunctions are evaluated simply by summing the weighted individual values of the sturmian and spherical harmonic functions, computed by recursion formulae over the locus of the equation $\frac{1}{2}\beta^2 r^2 \sin^2 \theta - 1/r = \varepsilon$. It is seen that the states of the principal series may be characterized by having no nodes along their turning lines, and have a significant concentration of amplitude on the ridge. If, on the other hand, one examines the wavefunctions for these states in the z = 0plane, it will be seen that each successive state has an additional node along the ridge. This is the source of the rather close agreement of the energies of these levels with that predicted by the simple two-dimensional WKB theory^{2,8}. The subsequent series admit a similar classification. The states of the second series exhibit two nodes along the turning line, those of the third exhibit four, and those of the fourth, six-the number of nodes increases by two between series because all these states are necessarily even under reflection in the plane. The states with odd numbers of nodes, not shown in Fig. 1, have wavefunctions which vanish on the ridge and have much smaller oscillator strengths; these would be obtained in absorption of light polarized in the direction of the magnetic field.

Thus, the magnitude of the oscillator strength associated with a given state is directly correlated with the localization of its wavefunction on the ridge at large distances. Moreover, the spread of the wavefunction off the ridge occurs in a regular manner for the states of greatest spectral prominence. The members of a given series differ by their degree of excitation along the rising ridge of the potential; the separate series are distinguished by the degree of excitation of the unstable motion across the ridge. This picture of two nearly uncoupled modes of oscillation, which holds at least throughout the energy range of Fig. 1, explains the observed weakness of interseries perturbations. Note that this classification is an approximate one, and that some states, for example the 15th member of the third series and the 16th member of the fourth, show marked departures from the regular scheme. However, these isolated irregularities occur, in every case examined so far, when lines from separate series coalesce. Although one cannot extrapolate these results to higher energies or other atoms with complete confidence, nevertheless, it seems probable that the major structures seen in photoabsorption cross-sections at energies above the ionization limit are due to resonance states which can be placed in a principal series. The secondary features which are seen would then be associated with the higher series, and should be expected to be broadened more rapidly with increasing energy due to the greater probability of escape off the ridge.

Localization of a quantum mechanical wavefunction in a region of maximum potential, although at first seemingly contradictory, is probably a phenomenon of general importance. For example, the occurrence of barrier top resonances in heavy ion direct reactions have been analysed by Friedman and Goebel¹⁰. Some qualitative remarks are suggested by the form of the line clusters in the low energy region of Fig. 1e. If viewed in the framework of degenerate perturbation theory, the energy levels within a cluster are isomorphic to the eigenfrequencies of a chain of oscillators with nearest-neighbour coupling¹¹. If the spring constants along such a chain were uniform, a sinusoidal distribution of energy levels would be obtained and the eigenmodes of oscillation would be standing waves. This occurs, for instance, in the simple Hückel model for a π electron system of conjugated double bonds, resulting in electron wavefunctions which are entirely delocalized. If, however, the coupling along the chain is non-uniform-corresponding to the insertion of a substitutional impurity in a Hückel molecule—the eigenmodes of oscillation must become partially localized. In our problem the analogous nearestneighbour coupling is non-uniform, and gives rise to a linear distribution of energy levels at the extremities of each cluster. The wavefunctions of states at the top and the bottom of a cluster are then necessarily localized, respectively, in the regions of maximum and minimum potential.

Failure of Arrhenius equation for hydroxyl radicalbicarbonate ion reaction above 100 °C

David Ritchie McCracken*

CEGB, Berkeley Nuclear Laboratories, Berkeley, Gloucestershire GL13 9PB, UK

George V. Buxton

The University of Leeds, Cookridge Radiation Research Centre, Cookridge Hospital, Leeds LS16 6QB, UK

Although the chemical kinetics of reactive species in water at temperatures above 100 °C has received very little attention, the radiation chemistry of aqueous coolant at the high pressures (150 bar) and temperatures (330 °C) of pressurized and boilingwater nuclear reactors is of obvious interest to reactor chemists, engineers and designers1. There is a wealth of data2 on rate constants for reactions of the radiolytically important radicals e_{aq}, H, OH, O⁻, HO₂ and O₂ at room temperature, but only a few rates have been measured up to 90 °C and only one up to 200 °C. It has thus become common⁵⁻⁹ to calculate the rate constants required for modelling water radiolysis in reactor conditions by extrapolating room temperature data using the Arrhenius equation $k = A \exp(-E/RT)$ where E, the assumed activation energy, has a value in the range 12-20 kJ mol⁻¹. We report here the failure of this method to predict the rate of reaction of hydroxyl radicals with bicarbonate at temperatures up to 200 °C.

We are making a systematic study of the reaction kinetics of the primary radicals and their secondary products, formed in the radiolysis of water, using pulse radiolysis-kinetic spectrophotometry over the temperature range 25-200 °C. Simultaneously, measurements are being made of the effect of temperature on yields of the primary radicals, as this is another area where data are sparse and conflicting 7,9-12

We began by studying the hydroxyl radical reaction with bicarbonate ion for two reasons: first, this reaction has already been investigated at room temperature¹³, and second, it will occur when alkaline water is exposed to air and radiation, as happens in nuclear power operations.

The rate of reaction (1) was measured by observing the formation of the carbonate radical ion CO₃ which has an optical adsorption band with a maximum at 600 nm, in nitrous oxidesaturated solutions of sodium bicarbonate at natural pH.

$$OH + HCO_3^- \rightarrow CO_3^- + H_2O \tag{1}$$

$$e_{aq}^{-} + N_2O \xrightarrow{H_2O} N_2 + OH + OH^{-}$$
 (2)

$$CO_3^- + CO_3^- \to CO_2 + CO_4^{2-}$$
 (3)

Conditions were chosen to ensure that reaction (2) was too fast, and reaction (3) too slow, to interfere in the measurement of k_1 .

The solution was contained in a conventional Pyrex-quartz flow system inside a pressure vessel and subjected to an overpressure of helium at 20 bar to prevent boiling. The temperature of the solution was measured with a thermocouple in a quartz sleeve which protruded into the radiolysis cell. The thermocouple was checked by observing the boiling point of water as a function of pressure and this showed that the error in the temperature readings was ≤2 °C. The radiation source was a Van de Graaff accelerator producing 0.6-µs pulses of 3-MeV

^{*} Present address: Atomic Energy of Canada, Chalk River Nuclear Laboratories, Ontario,

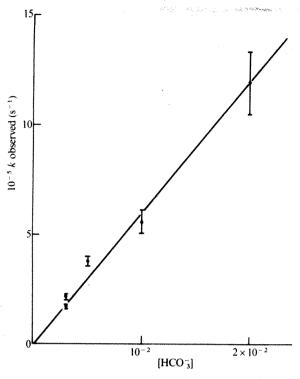

Fig. 1 Observed first-order rate constant for build up of CO₃ absorption at 308 K.

electrons. The dose per pulse was ~ 1 krad and five pulses could be given to each sample of solution without producing a detectable change in the results. The sample was renewed at each temperature.

There was no change in either the shape or the intensity of the spectrum of CO_3^- with temperature. As $G(CO_3^-) = G(e_{aq}^-) + G(OH)$, this indicates that there is little change in the yield of these primary species up to 200 °C.

The dependence of the observed pseudo-first-order rate constant on $[HCO_3^-]$ is shown in Figs 1 and 2 for 35 and 196 °C respectively. Second-order rate constants are plotted according to the Arrhenius equation in Fig. 3. Here the data have been corrected for changes in activity resulting from changes in the density of water ¹⁴ and the equilibrium constants ¹⁵ K_4 and K_5 .

$$H_2CO_3 \rightleftharpoons HCO_3^- + H^+$$
 (4)

$$HCO_3^- \rightleftharpoons CO_3^{2-} + H^+$$
 (5)

Activity coefficients were calculated using extended Debye-Hückel theory 16 with appropriate constants 17 for the temperature range 25-200 °C. The largest correction (for $3\times$

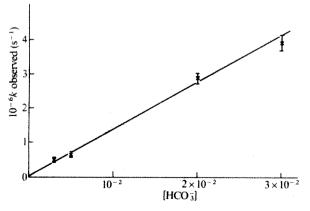

Fig. 2 Observed first-order rate constant for build up of CO_3^- absorption at 469 K not corrected for changing density or activity, with temperature. True $k = k_{\text{Obs}}/0.84$.

 10^{-3} mol dm⁻³ bicarbonate at 200 °C) was only 5%, and the most important factor was the density of water, for which the largest correction was 14%. In all cases $[CO_3^2^-] \le 0.01 \, [HCO_3^-]$ and we estimate the contribution of reaction (6) to the observed rate of formation of CO_3^- to be $(10\pm1)\%$ over the whole range of temperature and $[HCO_3^-]$ (based on our unpublished measurements of $k(OH+CO_3^{2-})$ in the range $25-200\,^{\circ}C$). Accordingly, the data in Fig. 3 have been reduced by 10%, although such a correction does not alter the shape of the Arrhenius plot and is less than the spread of the data $(\pm20\%)$ about the solid curve.

$$OH + CO_3^{2-} \rightarrow CO_3^{-} + OH^{-}$$
 (6)

There is no evidence for reaction of OH with carbonic acid and we assume that it can be neglected.

Figure 3 clearly shows that the data for k_1 do not obey the Arrhenius equation, but the deviation is not obvious below $100\,^{\circ}$ C. The low temperature data extrapolate to $k_1 \approx 10^9\,\mathrm{dm^3\,mol^{-1}\,s^{-1}}$ at $330\,^{\circ}$ C with an apparent activation energy $\sim 14\,\mathrm{kJ\,mol^{-1}}$, whereas the high temperature results give $k_1 \approx 2 \times 10^8\,\mathrm{dm^3\,mol^{-1}\,s^{-1}}$ and show scarcely any apparent activation energy. A reaction scheme which is consistent with the data is

$$OH + HCO_3^- \xrightarrow{k_a} X \xrightarrow{k_c} H_2O + CO_3^-$$

where X is an adduct of OH and HCO3. The adduct could be a

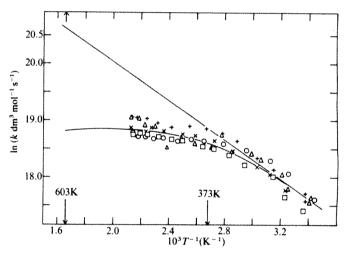

Fig. 3 In (corrected observed second-order rate constant) as a function of reciprocal temperature (K^{-1}) . The solid curve is a fit of the data according to the mechanism

OH+HCO₃
$$\stackrel{k_a}{\rightleftharpoons}$$
 X $\stackrel{k_c}{\rightleftharpoons}$ CO₃+H₂O.
 \square , 3×10^{-2} ; ×, 2×10^{-2} ; +, 1×10^{-2} ; \bigcirc , 5×10^{-3} ; \triangle , 3×10^{-3} mol dm⁻³ HCO₃.

carbon-centred radical, which rearranges to an oxygen-centred one and then splits off water to leave CO_3^- .

Then,

$$k_{\text{obs}} = \frac{k_{\text{a}}k_{\text{c}}}{k_{\text{b}} + k_{\text{c}}} = \frac{A_{\text{a}} \exp(-E_{\text{a}}/RT)}{1 + (A_{\text{b}}/A_{\text{c}}) \exp(E_{\text{c}} - E_{\text{b}})/RT)}$$

The solid curve in Fig. 3 has been calculated with $A_a = 1.3 \times 10^{11} \, \mathrm{dm^3 \, mol^{-1} \, s^{-1}};$ $A_b/A_c = 1.2 \times 10^3;$ $E_a = 18.9 \, \mathrm{kJ \, mol^{-1}};$ $E_b - E_c = 21.3 \, \mathrm{kJ \, mol^{-1}}.$ Unfortunately, the data

have not been obtained over a sufficiently large temperature range to fix these parameters to better than 50% for Ea and $E_b - E_c$ or within an order of magnitude for A_a and A_b/A_c . Experiments are planned which will extend the temperature range to ≥330 °C.

In spite of the present limitations in the data, they demonstrate quite clearly that the extrapolation of linear Arrhenius plots of rate constants measured at low temperatures (<100 °C) to obtain their high temperature values could be quite misleading, and that experimental measurements at temperatures pertaining to nuclear reactor operations need to be made if water radiolysis is to be modelled correctly in these conditions.

We thank Rod Brown, Brian Hale, Frank Hambleton and Philip Wright for technical assistance and advice.

Radio-echo layering in polar ice sheets and past volcanic activity

D. H. M. Millar

Scott Polar Research Institute, University of Cambridge, Lensfield Road, Cambridge CB2 1ER, UK

A recent study has shown how acidity profiles along dated Greenland ice cores can reveal large volcanic eruptions in the Northern Hemisphere during the past 10,000 yr. It has been suggested that these layers of acidic ice in the polar ice sheets may also be detected by airborne radio-echo sounding (RES) techniques as stratification echoes²⁻⁴. Explosive volcanic eruptions eject large amounts of SO2 into the stratosphere5 where it forms an H₂SO₄ aerosol⁶. Studies of Antarctic snow⁷ and Greenland ice cores² show that this material can be deposited in layers of large areal extent on polar ice sheets. Calculations based on observations of these slightly acidic layers show that they should give rise to radar reflections of similar magnitude to those observed for stratification echoes. New RES data from the Antarctic enables the present comparison to be made between observed layer power reflection coefficients (PRCs), and calculated values for reflections from acidic ice layers and from layers of ice of changed density. A gap in layering has been identified which seems to coincide with a similar gap reported in Greenland at Crête⁸; profiles of layer PRC against age show a common pattern for many sites on the Antarctic ice sheet. This PRC/age profile may provide a record of explosive volcanic activity for the Southern Hemisphere over the past 150,000 yr.

During a joint Antarctic RES Programme conducted by the NSF, the Scott Polar Research Institute and the Electromagnetics Institute of the Technical University of Denmark (TUD), calibrated A-scope radar displays (showing returned/transmitted power versus range, Fig. 1) from the 60 MHz TUD ice-sounding radar were recorded, from which PRCs for internal layers were obtained after allowing for geometrical

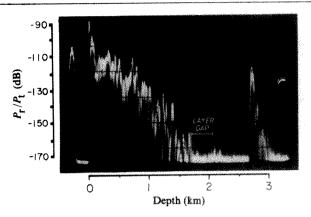

Fig. 1 Calibrated A-scope record from near Crête, Greenland. Note gap in layering at 1,700-2,100-m depth.

spreading and absorption losses to give profiles of layer PRC against depth (see Fig. 2a). Errors are estimated to be ± 10 m for depths and ±2 dB for PRCs; layer roughness causes the echo strength to fluctuate rapidly over a 10 dB range as the aircraft moves so that repeated, closely-spaced measurements are necessary to average out this effect.

Fluctuations in ice density have been suggested 9-11 as a cause of layer echoes in ice sheets, and stratigraphic analysis 12 of ice cores indicates that clear ice layers (millimetres thick) and similar features do occur in the upper parts. A simple expression for the maximum density contrast between clear ice and 'bubbly' polar ice as a function of depth9 (which compares well with estimates from the density profile of Byrd Station, Antarctica) has been used to compute the upper limit of PRCs from this mechanism (Fig. 2a, solid line). At Byrd observed PRCs are ~10-20 dB weaker than this limit, but decrease with depth in the same way; this is consistent with the observation of occasional density fluctuations in the core 10

At Byrd the ice is completely bubble-free below 1,100 m (ref. 13) and so this mechanism cannot apply to the deeper echoes seen. Paren and Robin¹⁴ suggested that deeper layer echoes are caused by layers of ice of changed loss tangent, due to changed impurity levels, and Hammer² thought that acids of volcanic origin may provide the impurity. It is suggested here that varying concentrations of such acids are the only plausible cause for changes in loss tangent detectable by RES. The highest acidity ice layers observed in the 400 m core from Crête are believed to coincide in depth with layer echoes, however, no comparison of reflection coefficients was attempted. In the absence of experimental measurements of the loss tangent of acidic polar ice, approximate estimates of the PRC for a layer of ice containing an elevated H⁺ concentration are made from laboratory measurements¹⁵ of the high frequency (h.f.) conductivity of HF-doped ice. The difference in loss tangent, $\Delta(\tan \delta)$, between pure ice and ice doped with acid is in theory16 related to the associated change in h.f. conductivity, $\Delta \sigma_{\infty}$:

$$\Delta(\tan \delta) = \Delta \sigma_{\infty} / 2\pi f \varepsilon' \varepsilon_0 \tag{1}$$

where ε' is the permittivity of polar ice, ε_0 the permittivity of

free space and f the radar carrier frequency. The high mobility of the H^+ ion is thought to dominate the h.f. dielectric properties of acid-doped ice, and so the nature of the anion will be expected to be of secondary importance. Impurities other than H^+ do not alter the loss tangent sufficiently (except in very high concentrations) to give detectable echoes. PRCs for a single interface (R_*) and a thin layer (R) of ice of changed loss tangent may then be obtained from the relations given by Paren and Robin:

$$R = 4\sin^2(2\pi l/\lambda)R_s \tag{2}$$

$$R_s = 1/16[\Delta(\tan \delta)]^2 \tag{3}$$

where l is the layer thickness and λ the radar wavelength in ice. Table 1 shows measured H⁺ concentrations associated with several large historical eruptions³, and estimated h.f. conductivities and PRCs; errors in estimating R_s are thought to be <5 dB. The estimated values are similar to those observed in the deeper ice below the region where density effects dominate. Little temperature dependence of PRC on H⁺ concentration is estimated at temperatures above -40 °C, so any variations of PRC with depth are expected to reflect past volcanic acid input to the ice sheet. PRC/layer age profiles from widely spaced Antarctic sites show many common features (Fig. 3), and this pattern may thus be interpreted as a record of the varying amounts of volcanic acid deposited on the ice sheet at different times.

Dated Z-scope layering from several Antarctic sites also reveals a common gap at ~15-20 kyr BP (this is not obvious on individual Z-scope records due to the close spacing of layers in the Antarctic), which seems to be simultaneous with a similar gap in layering at 1,900-2,300 m depth at Crête⁸ and dated¹⁷ at ~13-23 kyr BP. The uniqueness and coincidence of these gaps suggest a common cause: one possibility is chemical neutralization of volcanic acids by calcareous dust blown on to the ice sheets at the end of the last glaciation, due to exposure of former shallow water areas. Large increases in ice calcium levels are observed at Camp Century (Greenland) and Byrd at this time¹ and at Camp Century the ice is known to be slightly alkaline during this period. Such neutralization could affect the PRC/age profiles at other times, but this is thought to be unlikely because of the steadier Ca levels18 before 20 kyr BP, the probable link between Ca dust production and the end of the glaciation, and the lack of any other gaps in Z-scope layering. The PRC/age

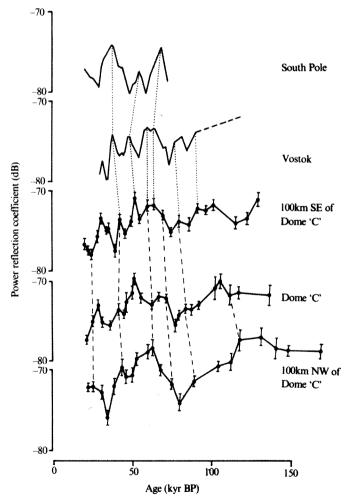

Fig. 3 PRC/age profiles for layers observed at South Pole, Vostok, Dome C and two sites $(1) \sim 100$ km south-east and $(2) \sim 100$ km north-west of Dome C. Bars indicate standard errors in power reflection coefficients and dashed lines join layers followed between sites on the Z-scope record. Dotted lines indicate suggested common features (data do not exist to enable layers to be followed on the Z-scope record).

pattern may therefore provide a useful indication of past volcanic acid input to the ice sheets, reflecting explosive volcanic activity in the Southern Hemisphere.

Conventional airborne echo sounding has already proved valuable in revealing the flow structure of the ice. The extension of the technique, using purpose-built radars (with better resolution) to the field of ice chemistry offers advantages of speed, economy, and the ability to sample the ice over representative areas, rather than at isolated points (with inherent uncertainties due to accumulation variability) plus deep penetration and consequently a long time scale. Such a technique should be complementary to drilling as core results are necessary to 'calibrate' the radar results.

I thank Dr G. de Q. Robin for supervision, and Drs C. U. Hammer, C. S. Neal, S. Overgaard and J. G. Paren for useful discussions and encouragement. Dr S. Overgaard (TUD) gave permission to reproduce Fig. 1. Logistic support was provided by the NSF and financial support in the form of a Research Studentship from the NERC was much appreciated.

Intermediate depth seismicity in the western Mediterranean unrelated to subduction of oceanic lithosphere

D. Hatzfeld

Laboratoire de Géophysique Interne, IRIGM, Université Scientifique et Médicale de Grenoble, BP 53X, 38041 Grenoble Cédex, France

M. Frogneux

Service de Physique du Globe, Institut Scientifique, av. Ibn Batouta, Rabat, Morocco

There are three zones in the Gibraltar area where intermediate depth earthquakes occur down to 150 km. Two of these, the Gulf of Cadiz and the western Alboran Sea, are oceanic areas which could be associated with the subduction of oceanic lithosphere. Our present measurements of arrival times of P and S waves show, however, that the third zone beneath the High Atlas is a typical intracontinental chain, where it is not likely that oceanic lithosphere has been subducted during the past 20 million years.

In the oceanic domain, West of 15 °W, the Azores-Gibraltar seismicity clearly outlines the Eurasian-African plate boundary. Towards the East, however, where the continental domain begins, previous studies have shown the presence of widely scattered epicentres¹⁻³ that have led to postulations of an Alboran buffer sub-plate. Precise relocations reduced the scatter and the seismicity can rather be interpretated as a reactivation of old tectonic faults^{4,5}.

Table 1 Velocity structure for HYP071

Mean continental		Oc	eanic	Thick continental		
z(km)	$v(\text{km s}^{-1})$	z(km)	$v(\text{km s}^{-1})$	z(km)	v(km s ⁻¹)	
0	6.10	0	6.10	0	6.10	
15	6.7	15	7.9	15	6.2	
30	8.0	30	8.0	45	8.0	
100	8.2	100	8.2	100	8.2	
200	8.3	200	8.3	200	8.3	
300	8.58	300	8.58	300	8.58	

z is the depth, v the velocity.

One major problem remains: the depth of the foci. Two deep earthquakes (h = 640 km) which do not fit easily in the active tectonics schemes, occurred beneath Granada, in southern Spain (29 March 1954 and 30 January 1973). Moreover, Munuera⁶ listed some intermediate depth earthquakes, but as the seismic network in Morocco and the location procedure were less developed, his locations are not very well established.

Arrival times, of both P and S waves, given in bulletins for stations in Spain, Algeria and Portugal are used here with our data in Morocco for the period 1972-78. The velocity structure used in the HYP071 routine (Table 1) represents an average continental structure as is the case in the Moroccan Meseta7 From more than 1,000 earthquakes of magnitude >3 detected in this area, we selected 401 events recorded in 5-25 stations (depending on the magnitude of the earthquake), with a residual smaller than 2 s. Among these we selected 247 earthquakes for which the standard deviation in location or depth, determined by HYP071, was <20 km (Fig. 1).

However, HYP071 error determination is a statistical evaluation of the error based on the dispersion of arrival times but does not take into account systematic bias due to the use of a wrong velocity structure or V_P/V_S ratio. We carried out a series of tests, on a few sample events in different regions (Alboran Sea, Gulf of Cadiz, High Atlas, Betic Cordillera, Rif) located with 5-15 arrival times. Starting with a synthetic zero-residual solution, we re-ran the location program, altering one parameter each time. The difference from the initial result gives us an estimate of the error associated with each parameter.

The first test examined the effects of errors in readings. Assuming that misreadings are <1 s for P waves and <2 s for S waves, random noise was added to synthetic travel times. The variations in computed location and depth were respectively <10 km and <20 km in all cases.

The effect of the V_P/V_S ratio was also investigated. Again synthetic travel times were used and locations recomputed using V_P/V_S ranging from 1.70 to 1.80. The resulting variations in locations and depth were similar to those obtained in the previous test.

The influence of the velocity structure was checked by calculating locations using the two extreme models given Table 1. These models correspond to a thin crust overlying an anomalously low upper mantle as in the Alboran Sea^{5,8} and to a thick crust as in the Betic Cordillera 10 or the Rif zone 5. Between these models the epicentres differ by 2 km and the depth by 13 km. HYP071 does not take into account lateral variations of velocity but it is unlikely that locations will be much altered by such variations.

One further question is related to the use of a flat layer velocity model, which could not be appropriate over an area ~1,000 km wide, because of the sphericity of the Earth. Chatelain et al. have shown that the resulting error for a 300-km wide network is less than 1 km. We assume the error to be of the same order in our case.

Figure 2a shows an east-west cross-section of the Alboran Sea. Most of the earthquakes are deeper than 50 km. One of them (7 August 1975) was recorded in 198 stations; its depth computed by the ISC is 94±2 km. Observations of pP and sP waves confirm this result⁵. Our determination using 13 stations is 105±4 km. The seismic zone lies between the peridotite

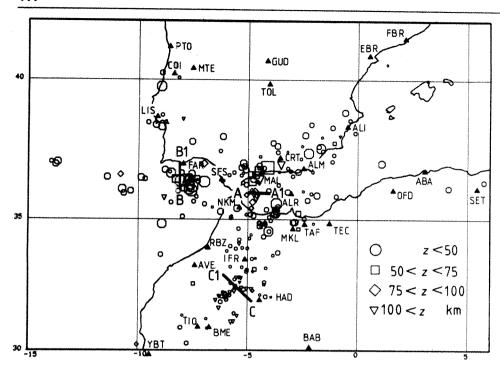

Fig. 1 Seismicity map of the Gibraltar area for the period 1972–78. Errors in location and depth (given by HYP071) are smaller than 20 km. Different symbols are functions of the depth of the focus; the size of the symbol is function of the number of stations which recorded the earthquake. A, Stations. The location of the cross-sections are shown.

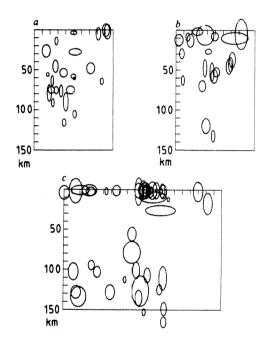

Fig. 2 Cross-sections for the three zones with intermediate earthquakes. a, The Western Alboran Sea; b, the Gulf of Cadiz; c, the High Atlas. The ellipses represent the error in location and depth given by HYP071.

massifs of Ronda (Spain) and Beni Bouchera (Morocco). A refraction profile in this area shows an anomalously high upper mantle velocity⁵ and that relative residuals at nearby stations are large¹¹, corroborating the existence of an anomaly in the velocity structure of this area.

Figure 2b shows a north-south cross-section of the Gulf of Cadiz. Most earthquakes there are shallower than 70 km, but three are deeper than 100 km. Commenting on the seismic intensity map of the 15 March 1964 earthquake, Udias and Lopez-Arroyo¹² suggest that its depth should be greater than the 27 km value inferred by the ISC.

In the High Atlas region we recorded 17 earthquakes deeper than 30 km in 7 yr. Because of their small magnitude (<3.5) these earthquakes are usually clearly recorded by only five

Moroccan stations. Thus it is important to have some confidence in the S arrival times. Figure 3 shows typical seismograms for an event at 125 km depth. Because of the significance of intermediate earthquakes in this region, the tests described earlier where applied individually to each event. Figure 2c shows a cross-section striking NW-SE across the High Atlas. Of the 17 events, 14 are deeper than 100 km, and there is a gap in activity between 30 and 55 km. The only three events in the 20-90 km range are on the north-east border of the seismic zone.

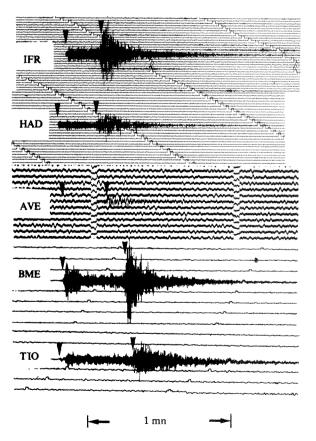

Fig. 3 Seismograms of the 1 August 1977 earthquake located at 125 km depth beneath the High Atlas. Notice the quality of P and S arrival times. Stations names refer to Fig. 1.

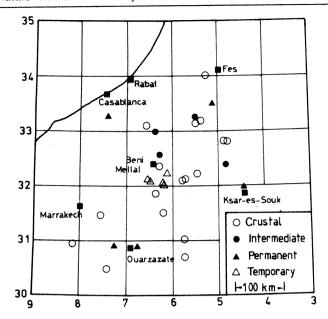

Fig. 4 Epicentres of a 15-day microearthquake survey in the High Atlas. Only events with a difference in arrival of P and S >5 s and error in depth <25 km are shown. ○●, Earthquakes; △▲, seismological stations.

To check the intermediate seismicity beneath the High Atlas, we carried out a microearthquakes survey for 15 days in 1978¹³. The network of six stations had an aperture of 30 km. During this period, 99 events were recorded in at least four stations; 43 of them have a travel time difference between P and S of <5 s and are shallower than 20 km. Among the 56 others, 51 are shallower than 20 km, one is 27 km deep and the last four are deeper than 110 km (Fig. 4). Their magnitude ranges between 1.7 and 2.5 and the closest station is at a mean distance of 60 km. The tests described above applied to these four events show a variation of 25 km in depth and 30 km in epicentre.

Two of the three zones where there are reliable intermediate earthquakes are close to the oceanic boundary between Africa and Europa and could be related to subduction (Gulf of Cadiz and Alboran Sea). On the other hand, the High Atlas whose basement and surroundings are continental is considered a typical intracontinental chain¹⁴. The existence of basaltic intrusions of Jurassic age¹⁵ is probably related to an extension episode into an entirely continental surrounding^{14,16}

Other zones, with intermediate depth earthquakes, are known in the Alpine-Himalayan belt such as Romania, Hindu-Kush, Tibet and Burma. In the Hindu-Kush and Romania a gap in seismicity is observed between 20 and 70 km and the activity decreases at 150 km and disappears at 200 km. This is similar to the results we observe in the High Atlas and differs from that in our two oceanic areas. Although we cannot exclude the possibility that deep seismicity represents the remains of subducting oceanic crust in all of these regions, it is open to question. In the High Atlas particularly, the possibility of a subduction zone in the past 20 Myr seems impossible.

We thank D. Bensari and H. Msougar for help in Morocco, J. Bonnin and M. Mattauer for valuable comments; and especially P. Molnar for his encouragements and suggestions. This research was supported by INAG, contracts ATP 32-01 and 32-23.

Palaeomagnetism of the Ibero-Armorican arc and the Hercynian orogeny in Western Europe

H. Perroud & N. Bonhommet

Laboratoire de Géophysique Interne-Centre Armoricain d'Etude Structurale des Socles, (CNRS), Université de Rennes I, Campus de Beaulieu, 35042 Rennes Cédex, France

Van der Voo1 has pointed out that further advances in the understanding of the Hercynian orogeny require palaeomagnetic data from well studied orogenic areas. We report here palaeomagnetic results of Palaeozoic rocks taken in Brittany, Portugal and Spain in the Ibero-Armorican arc (IAA), a large geological feature considered to be a key area for the Hercynian orogeny in Western Europe. They show evidence that the IAA formed in two stages, extending results obtained in Spain by Ries et al.². Giving precise constraints for the former shape of the arc we can use pre-Hercynian palaeomagnetic directions found in Spain and Portugal to follow its evolution during Palaeozoic times. This megastructure linking Brittany to Iberia. squeezed between Gondwana and the northern continents during the Carboniferous, did break away from the former block during Ordovician times.

Geological^{3,4} and geophysical⁵ evidence suggests that the IAA is formed of large juxtaposed curved units lying on the two sides of the Bay of Biscay. Stratigraphic studies of Palaeozoic formations from the arc^{6,7}, performed at the Rennes CNRS centre, suggest that the shape of this structure could have been quite different before the Hercynian deformation. In particular, the very strong correlations between the stratigraphy and palaeontology of the Crozon area (Brittany) and the Buçaco syncline (Portugal) for Ordovician rocks imply that these two regions belonged to the same sedimentary basin in the Lower Palaeozoic, and thus palaeogeographic reconstructions' tend to place these two regions next to each other. Moreover, the question of whether the arc is of primary or secondary origin is crucial for several of the models proposed for the Hercynian orogeny. A primary origin implies that the arc always had the same curvature whereas a secondary origin implies oroclinal bending following Carey's model⁸. Ries et al.² recently showed that the Iberian arc, the inner part of the IAA, had a predominant secondary origin. The absence of definitive evidence that the two structures did evolve simultaneously led us to extend the sampling to the whole IAA and to different stages in

Samples were from: (1) Brittany: Upper Ordovician dolerites of Crozon (14 sites, 100 samples); (2) Spain: Ordovician volcanics of Cabo de Penas (2 sites, 31 samples), Upper Devonian red sandstones of Candas (3 sites, 32 samples), Lower Carboniferous red grits, Alba formation from Candas (3 sites, 23 samples) and San Emiliano (6 sites, 42 samples); (3) Portugal: Cambro-Ordovician redbeds (7 sites, 60 samples) and Upper Ordovician dolerites (4 sites, 34 samples) from Buçaco (Fig. 1). Natural remanent magnetization (NRM) was measured for these samples and for most of them a viscosity test⁹ was also performed; a.c. field, thermal and chemical demagnetizations were carried out (all samples being treated by at least one of these methods, mostly by two). In addition, rock magnetic experiments such as coercivity spectrum analysis to of pairs of

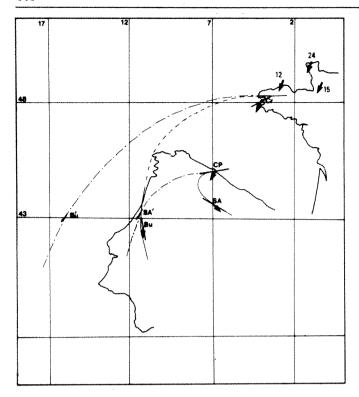

Fig. 1 Palaeomagnetic Carboniferous directions (thick arrows) found on the Ibero-Armorican arc with sampling locations (CR, Crozon; CP, Cabo de Penas and Candas; SA, San Emiliano; BU, Buçaco) after closing of the Bay of Biscay (fitted by Lefort²⁴). Values for additional data in Brittany correspond to the references given in the text (see also Table 1). The ante-tectonic shape of the arc deduced from the data is also given with the corrected Carboniferous directions (small arrows).

leached and unleached samples, heating to Curie temperature or cooling to the liquid air temperature of an acquired induced remanent magnetization (IRM), were carried out to support the interpretation of the multivectorial magnetization with physical arguments on the magnetic carriers. The results obtained from

these studies¹¹, which will be published in detail elsewhere, can be summarized as follows.

The magnetic behaviour of the Upper Ordovician dolerites from Buçaco and Crozon is identical. Intensities are low, with a maximum frequency between 10^{-2} and 10^{-3} A m⁻¹ and viscosities are high (>20% for 50% of the samples); the IRM acquisition curves are identical; they display the same magnetic transition at $-160\,^{\circ}$ C, suggesting the presence of magnetite, and current work at the Rennes CNRS centre gives K-Ar ages which range for both regions from 190 to 300 Myr. In accordance with the radio-dating results, the remanent magnetization is interpreted as being secondary with an acquisition period between Carboniferous and Triassic or Jurassic time (Table 1), thus confirming the geological relationships between Crozon and Buçaco.

Buçaco redbeds exhibit magnetization directions interpreted as pre-tectonic and remagnetization directions as being from the Upper Cretaceous and Quaternary¹¹. A characteristic of the pre-tectonic directions is a constant declination of 150° and variable inclination. The same behaviour was found by Duff¹² in an extensive palaeomagnetic survey of redbeds in Brittany with ages extending from Lower Cambrian to Lower Ordovician. From this work two sites at Crozon are well suited for comparison with Bucaco as both areas are thought to be part of the same sedimentary basin⁷, and thus allow comparison with data from contemporaneous redbeds. Components B3 and C found by Duff¹² on 10 specimens of these two sites using acid leaching, thermal and a.f. cleaning, gave a mean direction of 220° after tectonic correction (sites CP, CR in Tables 2 and 3 of ref. 12). The difference in declination between the two areas suggests a partial secondary origin of the IAA if we correct for the rotation of Spain during the Cretaceous and look at the variation of strike of the arc. Again, the palaeomagnetic characteristics of contemporaneous samples from Brittany and Portugal are identical.

At Cabo de Penas, Ordovician volcanics show two well defined pretectonic directions of magnetization (Table 1). One (component A) has a very steep inclination, coercivities over 70 mT and unblocking temperatures over 500 °C, and has been interpreted as Ordovician; the other (component B) has a shallow inclination and is comparable with the direction obtained east of Cabo de Penas for the Upper Devonian and Lower Carboniferous redbeds of Candas (component A); the

Palaeomagnetic component directions found on the Ibero-Armorican arc. N, Number of samples used; D, I, declination, inclination; k, α_{95} Fisher statistical parameters²³; \bar{S} , mean structural direction. Statistics may refer to samples, specimen, directions or sites: see in each case original work given in the reference; only the total number of samples used is given here; all data were cleaned using a.f., acid and thermal cleaning as done by Duff^{12.16}, N.B. et al. 4 and Jones et al. 5 and a.c. field up to 0.2 T (2,000 oe) as in ref. 22.

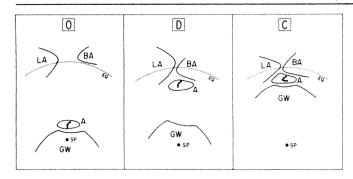

Fig. 2 Scheme of the evolution of the main plates involved in the Hercynian orogeny in Palaeozoic times (O, Ordovician; D, Devonian; C, Carboniferous) with mention of the Ibero-Armorican arc. LA, Laurentia; BA, Baltica; GW, Gondwana; A, Armorica.

eight sites (volcanics and sedimentary) were used to give a mean direction which is pre-tectonic as shown by a fold test. We can do better than the classical tilt correction on this example to calculate the mean direction: if we look at the angle between the strike direction and the magnetization on each site, this angle seems to be very constant $(52.5^{\circ} \pm 5^{\circ})$ regardless of the site and even though strike directions vary on this example between 210° and 244°. This suggests that deformation occurred in two stages, the latter one with a vertical axis correlated with the tectonic closure of the arc13, and that the magnetization was acquired before deformation; taking this result into account and using a regional mean direction for strike of 230°, the mean palaeomagnetic direction of the eight sites in Table 1 has been obtained after correcting each site for strike variation. The six sites of redbeds near Candas also show a soft component obtained on a few samples but scattered among all the sites (Candas redbeds component B, Table 1); the post-tectonic origin of this component is clearly indicated by a negative fold test¹¹. The corresponding inclination is very close to that obtained at Crozon on the dolerites (Crozon dolerites component B, Table 1); this last component has also been interpreted as post-tectonic but with a magnetization predating the closure of the arc, as shown by using a 'strike direction' correction on the 14 sites of Crozon. Magnetization was therefore acquired at Crozon between two main phases of deformation of the IAA.

The direction given in Table 1 for San Emiliano was obtained by N.B. et al. 14 using an unfolding model which took into using an unfolding model which took into account the two phases of deformation in the area; the effect of the model was to increase the precision parameter k (from 14 to 64) in comparison with the usual tilt correction. A pre-tectonic direction was found (Table 1) and a Lower Carboniferous age for the magnetization inferred from the age of the sediments.

Ries et al.² sampled the same Alba formation at Carranques near Candas and at San Emiliano; however, their result cannot be used for comparison because only three samples at Carranques were thermally cleaned and the authors report a direction $D = 211^{\circ}$, $I = 48^{\circ}$ with k = 2 showing large scatter after thermal cleaning; this is a general behaviour of all results obtained after cleaning as reported in that study. At San Emiliano four sites have been studied for the NRM but none appears among the thermal cleaned results given in Table 2 of their study.

Carboniferous data from Brittany obtained by Jones et al. 15 on the syncline of Montmartin and by Duff¹² from the Ploumanach granite, Jersey dolerites and volcanics, together with our own results at Crozon and Candas (CR, CP, Fig. 1) reveal (Table 1) that the corresponding directions are not significantly different for the northern part of the IAA before, (Candas A) and after (Candas B, Crozon B) deformation: most of the rotation seems to have occurred in the southern part of the arc. A new shape of the IAA can then be inferred taking the simplest compatible solution with the palaeomagnetic data. This

indicates that 80° of the curvature of the arc are secondary and that 70° are primary or pre-Carboniferous.

Ries et al. used results based on NRM directions from 29 sites along the Iberian arc to demonstrate convincingly the partially secondary origin of this structure; however, because these authors did not consistently use cleaned results to look for multicomponent magnetization, because they infer a Variscan age for all magnetizations, their data cannot be used for comparison as they give no directions associated with the age of magnetization for the different rock units studied. However, their result, a bending of 110°, is not very different from the 80° reported here.

From the new position of the sampling areas and the palaeomagnetic vectors calculated for the new shape of the arc (that is, after elimination of the Hercynian deformation), we can determine virtual palaeomagnetic poles for our Ordovician sites. The Buçaco (25°N, 335°E) and Cabo de Penas (30°N, 330°E) poles coincide in the new reconstruction, indicating that the shape of the arc we deduced from the Carboniferous data is also compatible with our Ordovician results. We therefore propose that 70° of the arc are effectively primary (presedimentary), inherited from Precambrian times. The mean Carboniferous declination of the north limb of the IAA differs by a few degrees (10°-15°) from that of stable Europe as shown by Jones et al. 15 for Montmartin syncline; it is not clear, however, whether the bending took place entirely in the southern part of the arc with a further rotation of 15° of the whole Ibero-Armorican block or whether it was the closure of the arc that caused the 15° difference with Europe. However, this does not change the former shape of the IAA found from the data. The Crozon B and Candas B components, both post-tectonic but ante-closure of the arc, in agreement with results of Jones et al. at Montmartin, show that at that time the IAA with its primary shape was close to Europe, with a large ocean separating it from Gondwana, a result shown for Brittany by Jones et al. 15 (Fig. 2).

The Ordovician mean palaeomagnetic pole obtained (27°N, 332°E) falls between Cambrian and Siluro-Devonian poles found by Duff¹⁶ for the Armorican massif and this agrees with the Ordovician age assumed for the magnetization. Interestingly, this pole is quite different from conventional Ordovician poles for the British Isles¹⁷ but could more easily be correlated with north Wales data, which have until now been considered as anomalous¹⁸. Recent results by Hagstrum et al. 19 showing that the apparent polar wander curve of the Armorican massif is very similar to the Eo-Cambrian-Cambrian curve for Gondwanaland prompted us to compare the Ordovician palaeolatitude for the IAA (70°) with the African Ordovician pole²⁰; this shows that the IAA should have been very near to Gondwanaland in the early Palaeozoic. These results show, moreover, that the Armorican massif and Iberia Meseta were probably a single unit during the entire Palaeozoic, thus justifying the name of 'Armorica plate' given by Van der Voo²¹ to these regions of Western Europe; the large drift of this plate since the Ordovician shows that collision and subduction tectonic processes did exist during the Hercynian orogeny. Finally, taking into account all these results and using available data given by Van der Voo¹, we propose a scheme of the main plates involved in the Hercynian orogeny with particular reference to the Armorica plate bearing the IAA (Fig. 2).

The research was supported by a grant from INAG through 'ATP Géodynamique' national programme. We thank Dr Van der Voo for suggestions and comments.

Dietary carbon sources of mussels and tubeworms from Galápagos hydrothermal vents determined from tissue ¹⁴C activity

P. M. Williams*, K. L. Smith*, E. M. Druffel† & T. W. Linick†

* Scripps Institution of Oceanography and

† Department of Chemistry, University of California, San Diego, La Jolla, California 92093, USA

The large quantities of reduced carbon that are required to support the filter-feeding mytilid mussels (Mytilus sp.), vesicomyid clams (Calyptogena sp.) and various other animals in the Galápagos hydrothermal vent systems are thought to be derived from either the in situ synthesis of particulate organic matter by chemoautotrophic, sulphide-oxidizing bacteria 1,2 or by the advection of sedimentary organic carbon into the vent environment from surrounding areas 3.4. In contrast, the dense populations of vestimentiferan tubeworms (Riftia pachyptila), which lack mouth organs and digestive tracts, apparently utilize organic carbon synthesized by symbiotic chemoautotrophs⁵. We present evidence here, based on ¹⁴C activities and ¹³C/¹²C ratios, that the principal source of dietary carbon for mussels and tubeworms is derived from the dissolved inorganic carbon (DIOC) in the vent effluent waters.

There are two postulated sources of particulate organic carbon (POC) available as dietary carbon to filter-feeding organisms. The first is sedimentary POC derived from DIOC fixed photosynthetically at the ocean's surface which subsequently reaches the ocean floor. Its radiocarbon activity is assumed to be the same as that of the DIOC in surface water $(+20\pm20, \text{ Table 1})$. The δ^{13} C of this POC (-22, Table 1) is a mean value derived from δ^{13} C measurements of POC^{6,7} collected below 500 m. The second source is POC synthesized chemoautotrophically from DIOC in the vent waters. This DIOC originates from both magmatic activity $(\Delta^{14}C = -1,000)$ or 'dead' carbon) and the ambient bottom water ($\Delta^{14}C = -233$, Table 1) which mixes with the high-temperature hydrothermal fluid. As the organic 14 C activities of the organisms grown in the vent systems reflect the Δ^{14} C of these three carbon sources and the 15C/12C ratios reflect the carbon isotope fractionation occurring during synthesis of organic tissues in these organisms, it is possible to calculate the relative contribution of each carbon source using the following equations:

$$\Delta^{14}C_{\text{mussel}} = x(-1,000) + y(-233) + z(20) \tag{1}$$

$$\delta^{13}C_{\text{mussel}} = (x+y)(\delta^{13}C_{\text{vent POC}}) + z(-22)$$
 (2)

where x, y and z are the relative amounts of magmatic DIOC. ambient DIOC and sedimentary POC, respectively. The δ^{13} C of POC in the vent water is unknown. Both of the above equations have to be satisfied to determine the relative amounts of the three possible dietary carbon sources utilized by the filterfeeding organisms.

The quantitative contribution of sedimenting POC to the food supply for filter-feeding vent organisms is questionable considering the flux of POC to the ocean floor and the in situ respiration rates of mussels. The total, mean flux of POC to the sea floor at 2,670 m 0°35.75' N, 86°05.66' W measured 20 and 100 m above the bottom on 4 July 1976 was $2.0 \text{ g C m}^{-2}\text{yr}^{-1}$ (ref. 9). In situ measurements of individual mussel respiration rates by K. Smith (unpublished results) range from 0.30 to 0.81 ml O₂ h⁻¹ in dense mussel beds. Assuming a respiratory quotient of 0.85, then these rates are equivalent to an organic carbon requirement of 1.2-3.3 g C yr⁻¹ (mean = 2.3 g C yr⁻¹). Thus, each mussel would essentially require the total annual POC flux per square metre for maintenance with no growth.

The 14C activity of the mussel tissue could result from a mixture of sedimentary POC and POC of low 14C activity derived from DIOC in the vent waters. The maximum amount of magmatic DIOC in the Galápagos vent waters (T = 17 °C) has been estimated to be 375 μ mol kg⁻¹, a 13% increase above the ambient DIOC concentration of ~2,400 μ mol kg⁻¹ (refs 10, 11). If 13% of the vent water DIOC is magmatic (Δ^{14} C = 1,000) and the remaining 87% is composed of ambient DIOC $(\Delta^{14}C = -233)$ plus sedimentary POC derived from the DIOC in surface water ($\Delta^{14}C = +20$), then the maximum amount of sedimentary POC that could be incorporated into mussel tissue $(\Delta^{14}C = -267)$ is 26% (equation 1). Estimates of mussel density in the 'Musselbed' vent area (W. Smithy, personal communication) are 20 ± 9 specimens per 0.25 m^2 in the immediate vicinity of the vent plume. If the mussels are utilizing the calculated maximum of 26% of sedimentary POC for growth (taken here as equivalent to maintenance), then each vent musselbed would use $\sim 48 \text{ g C m}^{-2}\text{yr}^{-1} (0.26 \times 2.3 \text{ g C yr}^{-1} \text{ per}$ mussel × 80 mussels per m²), or about 35% of the annual primary productivity per square metre in the euphotic zone9 for the growth of mussels alone.

There is a significant difference between the ¹³C/¹²C ratios, as well as ¹⁴C activities, of mussel tissue collected 1 and 8 m from the vent plume (Table 1). If sedimentary POC (δ^{13} C = -22) was incorporated into the tissue of the 8-m mussel, the resulting δ^{13} C value (-32.3) would be less than that observed (-32.8). This calculation assumes that the 14C activity of the 8-m mussel tissue ($\Delta^{14}C = -228$) is derived from a mixture of 14% sedimentary POC (Δ^{14} C = +20) and 86% chemosynthetic POC $(\Delta^{14}C = -267)$ (equation 1).

If the ¹⁴C activity of mussel shell carbonate reflects the ¹⁴C activity of DIOC in the surrounding seawater, then the 21% decrease in Δ^{14} C between the ambient seawater DIOC and the mussel shell carbonate reflects dilution of the ambient DIOC with 3% magmatic DIOC. For the two clam shell carbonates, the 30% decrease in Δ^{14} C would represent dilution of the ambient DIOC with 4% magmatic DIOC, taking the 14C activity of the bottom water at 21° N to be the same as at the Galápagos rift zone. A similar calculation gives 4.4% magmatic DIOC incorporated into cellular carbon synthesized by the chemoautotrophic bacteria and used by the mussels 1 m from the plume (provided the contribution from sedimentary POC is negligible).

The identical 14C activities of the vestimentiferan tubeworm tissue and the mussel tissues collected 1 m from the vents strongly suggest that the tubeworms and mussels are utilizing the same DIOC sources, even though δ^{13} C in the tubeworm tissue is 23% greater than in the mussel tissue (Table 1). These atypical 13 C/ 12 C ratios found in the vent organisms have been discussed by Rau^{12,13}. If bacterial chemosynthesis is the major process providing dietary carbon for the mussels and tubeworms, it is still unclear why carbon isotope fractionation should be different between chemoautotrophic synthesis occurring in the vent waters and internally (symbiotically) in the tubeworms.

An additional carbon source which may contribute to the bacterial synthesis of POC in the vent waters is methane, energetically a more favourable substrate for the growth of heterotrophic bacteria than DIOC. Methane concentrations up to 3.4 µmol kg⁻¹ have been measured in the Galápagos vent

The three mussels for tissue analysis were collected 1 and 8 m from the 'Musselbed' vent plume, Alvin dives 880 (21 January 1979) and 895 (20 February 1979), 0°47.89' N, 86°09.21' W at 2,493 and 2,480 m. The mussel for shell analysis was collected 1 m from the 'Musselbed' vent plume, Alvin dive 991 (8 December 1979) at 2,490 m. The tubeworm was collected in the 'Garden of Eden' vent plume, Alvin dive 993 (10 December 1979), 0°47.69' N, 86°07.74' W at 2,518 m. The clam for shell analysis was collected from the East Pacific Rise hydrothermal vent system, Alvin dive 981 (5 November 1979), 20°50' N, 109°06' W at ~2,600 m. The mussel tissue and tubeworm specimens were frozen after collection, and the tissue and shell samples rinsed with $^{14}\text{CO}_2$ -free, organic carbon-free distilled water before drying. To determine $\&\Delta^{14}\text{C}$ and $\&\delta^{13}\text{C}$, all samples but the tubeworm tissue were burned in O_2 or acidified with HCl to give CO_2 which was converted to acetylene, via lithium carbide 13 and then counted for 2 days in each of two stainless-steel 1.0-1 and 0.4-1 gas proportional counters. The worm tissue CO2 was purified by absorption onto CaO, diluted with background gas and counted twice in a 200-ml copper proportional counter for a total of 12 days. All countings were corrected for isotope fractionation (to a standard value of $\delta^{13}C = -25.0\%$ PDB-1) and for decay since the time of formation (to AD 1950). The standard was 95% of the net National Bureau of Standards oxalic acid count rate, corrected to a $\delta^{13}C = -19.0\%$, and the results are reported in terms of $\Delta^{14}C (\pm 1 \sigma \text{ counting error})$ which is the per million (%) deviation from the ¹⁴C activity of nineteenth-century wood ¹⁶. The ¹³C/¹²C ratios are reported as $\delta^{13}C (\pm 0.2\%)$ relative to the PDB-1 standard.

* The Δ^{14} C of the 2,490-m bottom water at the 'Musselbed' was assumed to be identical to the Δ^{14} C in 2,584-m water at Geosecs station 337, 24

May, 1974, 04°50' N, 124°05' W. σ_T at 2,500 m at both locations is 27.76±0.01 (ref. 17). † Δ^{14} C values taken from corals collected from 3-5-m depth at 1.5° S, 90-91° W, assuming the Ca¹⁴CO₃ reflects the ¹⁴C activity of the surface seawater DIOC.

waters (M. D. Lilly, M. A. de Angelis and L. I. Gordon, unpublished results), and it has been calculated that 50 µmol kg⁻¹ of abiogenic CH₄ of magmatic origin could be present in the 'end member' 350 °C hydrothermal fluid at the East Pacific Rise¹⁸. If methane were the sole carbon source for the synthesis of POC utilized by the mussels, then the mussel tissue would contain no measurable radiocarbon activity. Obviously this is not the case. It is possible that the 14C activity of the mussel tissues (-267) is 13% lower than that of the mussel shell carbonate (-254) due to mussels taking up both 'dead' CH₄ and DIOC, whereas the shell is only using 'dead' DIOC.

On the basis of the ¹⁴C activities and ¹³C/¹²C ratios reported here, we conclude that: (1) filter-feeding organisms in the vent system are directly or indirectly incorporating 'dead' carbon of magmatic origin into their tissue; (2) $\sim 25\%$ or less of the dietary carbon available to the mussels is from sedimenting POC fixed photosynthetically at the surface; and (3) mussel tissue is incorporating relatively more 'dead' DIOC than is mussel shell carbonate in specimens collected at the same location near the

A natural biological control of Dutch elm disease

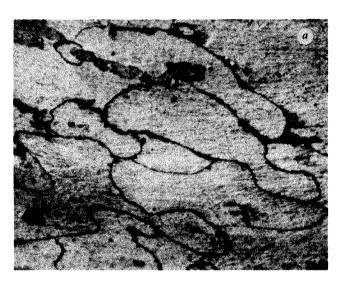

Joan Webber

Department of Botany and Microbiology, University College of Wales, Aberystwyth SY23 3DA, Dyfed, UK

Since its arrival in the late 1960s, the aggressive strain of Ceratocystis ulmi, the fungus that causes Dutch elm disease, has destroyed over 20 million elms in Britain and subsequently inflicted similar heavy losses across much of continental Europe^{1,2}. Successful control of the disease has been achieved only locally, using intensive sanitation and fungicide injection programmes^{3,4}. However, it has recently become apparent that disease spread may also be limited naturally. I present here evidence of a biological control of Dutch elm disease which could be exerting an important effect in some parts of Britain. This control process acts by preventing successful breeding of scolytid beeties which are the vectors of C. ulmi.

The control phenomenon was first encountered during 1976 and 1977 in several stands of trees in mid and south Wales. Each stand contained between 10 and 100 wych elms (Ulmus glabra) and although C. ulmi had killed some trees in all these stands, disease spread to healthy trees was surprisingly slow, suggesting that only small numbers of beetle vectors were present. Investigation of beetle breeding material, that is, the inner bark of dying or recently dead trees, revealed only a limited amount of active breeding. Instead such bark commonly exhibited dark zone lines (Fig. 1a), which on isolation yielded the fungus Phomopsis oblonga. The presence of Phomopsis was also clearly associated with the disruption of beetle breeding and disruption usually took one of two forms. Most commonly, when Phomopsis and a breeding gallery occupied the same area of bark, beetle larvae were retarded in their development and constructed very elongated, contorted galleries. Less commonly observed was the evasive action of larvae on encountering a discrete Phomopsis lesion. In such circumstances larval galleries swerved away from the Phomopsis-colonized area into uncolonized tissue.

To compare effectiveness of scolytid breeding in *Phomopsis*-colonized and uncolonized bark, breeding experiments were done using the two British species of beetle vector, *Scolytus scolytus* and *Scolytus multistriatus*. The breeding material was of two types: logs cut from wych elm with recent, extensive bark colonization by *Phomopsis*, and control logs also from wych elm but with no observable *Phomopsis* colonization. Pairs of logs (one of each type) were presented to beetles in either a 'choice' or a 'forced' breeding situation. In the former, a standing pair of logs was enclosed in a fine net bag and beetles introduced. This allowed beetles to choose as breeding material either the *Phomopsis*-colonized log or the control log. In the forced breeding situation each log was enclosed individually in a bag, so that introduced beetles had no choice of breeding material. The

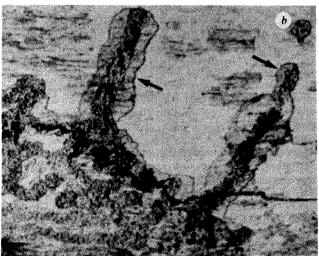

Fig. 1 a, Characteristic zone lines produced by *Phomopsis* colonizing the inner bark of diseased elms. These dark lines are thought to result from antagonistic interactions between different forms of the fungus present in the bark 7 . $\times \sim 2$. b, Modified zone lines (arrowed) formed around the larval galleries of *Scolytus*. Such modified zone lines are probably formed by *Phomopsis* in response to changes in the moisture content of the bark as a result of gallery excavation. $\times \sim 2.4$.

Table 1 Effect of *Phomopsis* colonization on scolytid breeding in elm bark

Breeding situation in log pairs	Maternal galleries per 100 cm ² bark	Total no. of emergent beetle progeny
S. scolytus		
Forced breeding		
Uncolonized control log	1.0	756*
Phomopsis-colonized log	1.3	0*
Choice breeding		
Uncolonized control log	1.8	1,690*
Phomopsis-colonized log	0.7	0*
S. multistriatus		
Forced breeding		
Uncolonized control log	2.5	780
Phomopsis-colonized log	2.3	17*
Choice breeding		
Uncolonized control log	4.3	1,048
Phomopsis-colonized log	1.7	0*

Four pairs of logs were used in all. The mean area of bark on logs presented to *S. scolytus* was 3,286 cm², and on logs presented to *S. multistriatus* was 2,290 cm². The number of maternal galleries per 100 cm² bark is a mean.

numbers of beetles introduced in these conditions depended on the total bark area available and the beetle species used. In the case of S. scolytus, one beetle pair, consisting of male and female, was allotted to each $100 \, \mathrm{cm^2}$ of bark, whereas one pair per $25 \, \mathrm{cm^2}$ of bark was used for the smaller bark beetle, S. multistriatus.

After 6 weeks the beetle breeding cycles were completed and the bark was stripped from the logs and gallery formation compared. It was immediately apparent that the breeding of both Scolytus species was strongly influenced by Phomopsis. When female beetles attempted to cut maternal galleries in a Phomopsis-colonized log many were abandoned at various stages before completion. If galleries were completed and eggs laid, the number of resulting larvae was drastically reduced and few developed into new adult beetles. In contrast, breeding in control logs was successful, and many young adult beetles emerged (Table 1). Figure 2b clearly shows the attempts at maternal gallery excavation in bark colonized by Phomopsis. Abnormal larval galleries are evident, typified by their elongated, twisted nature when compared with larval galleries in uncolonized bark (see Fig. 2a). Galleries affected by Phomopsis were also characterized by their frequent association with modified zone lines. Rather than appearing as the irregular ovals shown in Fig. 1a, zone lines often enclosed an entire gallery system, outlining each larval mine separately (Fig. 1b).

Behaviour of beetles in choice breeding experiments also suggested that *Phomopsis*-colonized bark was usually avoided as breeding material when an alternative was offered. The mean number of maternal galleries per 100 cm² of bark was similar in both *Phomopsis* and control logs in forced conditions, whereas in choice breeding experiments the number of galleries cut in control logs was over twice that attempted in *Phomopsis* logs (Table 1).

Thus *Phomopsis* is clearly able to exert a twofold effect on scolytid beetles by decreasing numbers of viable offspring in brood trees, or by eliminating potential breeding material and therefore intensifying competition for any uncolonized bark. Both factors must invariably have some role in reducing vector populations but we can only speculate on how much this may affect the continuing spread of Dutch elm disease.

One of the major factors which must undoubtedly govern the effectiveness of *Phomopsis* as a control agent is its frequency of occurrence, possibly as a latent inoculum in the dead outer bark of healthy trees. High levels of such inoculum would favour

^{*} Some living larvae (<20) still remaining in log.

Fig. 2 a, Breeding galleries of S. multistriatus produced in the bark of wych elm (U. glabra) with no Phomopsis colonization. Typically each sallery consists of rows of larval mines (or galleries) radiating outwards from points of egg laying along the length of a central mother gallery. Many of the larval mines terminate in oval pupal chambers. $\times \sim 0.25$. b, Sparse and abnormal breeding galleries of S. multistriatus in the bark of wych elm colonized by *Phomopsis*. Such galleries commonly show abortive or elongated and contorted larval mines. $\times \sim 0.25$.

rapid colonization of trees if they succumbed to Dutch elm disease. Phomopsis has frequently been found in the outer bark of healthy elms, but survey data have shown that it is largely limited to the elms in western and northern parts of Britain (J. F. W. and J. N. Gibbs, in preparation). It is therefore more likely to contribute to natural disease control in these areas. Furthermore, the massive colonization of elm bark required to exert an appreciable effect on beetle breeding has only been observed in wych elm, and it seems that Phomopsis is more strongly assoclated with this species of elm than any other in Britain. The fact that wych elm comprises the main part of elm populations in northern England, Wales and Scotland, also suggests that Phomopsis may be effective only in the north and west.

It has long been known that the spread of Dutch elm disease has been slower in northern England and in Scotland⁵. Previously this has been ascribed to various factors, including a smaller and more scattered elm population, a climate less favourable to the vectors and the preponderance of wych elm rather than English elm (*Ulmus procera*), the latter predominating in the south^{3.6}. It now seems that *Phomopsis* in an additional, and in some areas possibly the major factor in slowing the spread of the disease in the north.

I thank Drs J. N. Hedger and J. N. Gibbs for advice and encouragement. This work was supported by a SRC CASE studentship award.

Regenerative and passive membrane properties of isolated horizontal cells from a teleost retina

Daniel Johnston* & Dominic Man-Kit Lam†

Program in Neuroscience, "Department of Neurology and †Cullen Eye Institute, Baylor College of Medicine, Houston, Texas 77030, USA

Neurones in the intact retina are interconnected by a complex network of chemical and electrical synapses. The electrical interactions between many types of retinal neurones make it difficult to determine the active and passive membrane properties of the individual cells. A direct way to examine such properties is to dissociate the retina into single cells1-3 and to record intracellularly from identified, isolated neurones in the absence of neural connections. Such an approach has been used to study the electrophysiological properties of several classes of neurones in the vertebrate retins³⁻³. We have combined the method developed previously for examining the neurochemistry of individual retinal cells^{1,2} with a single-electrode clamp technique^{6,7} to investigate the biophysical properties of isolated horizontal cells from the teleost retina. Our results suggest that the specific membrane capacity of these cells is $\sim 1 \mu F \text{ cm}^{-2}$, and that the specific membrane resistivity ranges from ~5,000 to 20,000 Ω cm². In isolation, these cells can show regenerative voltage responses which are most probably calcium-dependent.

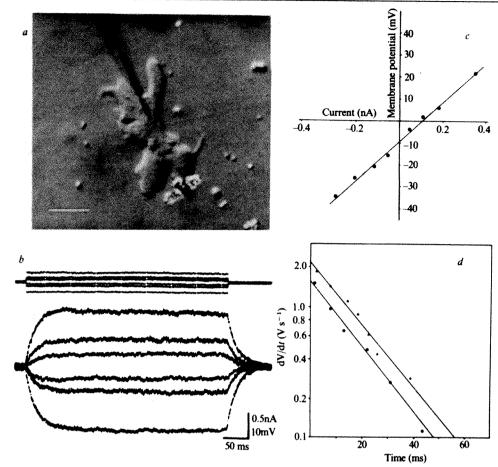

Fig. 1 Morphology and passive membrane properties of an isolated cone horizontal cell from the catfish retina. These cells were prepared by incubating isolated retinae with free Ringer's solution supplemented with 5 mM EGTA and 1 mg ml-1 (Worthington) at room temperature for 60-90 min. The retinae were then washed with Ca²⁺-free Ringer's solution containing 1 mg ml⁻¹ bovine serum albumin and trans-Ringer's solution containing ferred to a 15-ml conical tube. Isolated cells were obtained by gently pipetting the retinae through a wide-bore Pasteur pipette in 2 ml of a medium containing 90% 0.3 M sucrose and 10% Ringer's solution. The cell suspension was kept on ice for 2 min before the top 1 ml was transferred to 9 ml oxygenated Ringer's solution (120 mM NaCl, 4 mM KCl, 2 mM NaHCO₃, 5 mM CaCl₂, 5 mM glucose, 15 mM HEPES buffer, pH 7.7) supplemented with 10 µg ml⁻¹ deoxyribonuclease². a, Photomicrograph of a cone horizontal cell before impalement, with a microelectrode above. The surface area of this cell was calculated to be 16,000 µm². b, Voltage transients (bottom traces) recorded intracellularly from the cell shown in a in response to 400-ms constant current pulses (top traces). The cell was at its resting potential of -10 mV. c, Steady-state V-I plot from data shown in b. The slope indicates an input resistance of 89.6 MO. d. The first derivative of two voltage transients was determined graphically as described elsewhere^{7,13} and its log plotted against time. •, Data points from a 10-mV depolarizing voltage transient; A, data points from a 15mV hyperpolarizing transient. The data points can be fitted by single exponentials, suggesting isopotentiality for this cell. The average time constant was 17.7 ms.

In our electrophysiological studies, we started by isolating cone horizontal cells from retinae of the channel catfish for three reasons. First, the catfish retina contains only one type of cone (maximum absorbance 620 nm) and therefore only one type of cone horizontal cell that can be easily distinguished, even in isolation, from the more stellate rod horizontal cells. This ensures that our recordings are from a homogeneous population of horizontal cells. Second, the somata of these horizontal cells, which are probably GABA ergic⁹, receive input from dopaminergic terminals (D.M.K.L., in preparation). Therefore this preparation has a potential use in analyses of dopaminergic responses in a neurone from the vertebrate central nervous system. Third, these cells are relatively large in size (50–100 µm in diameter), making it possible to use low-impedance microelectrodes for voltage-clamp studies.

Catfish retinae were dissociated into single cells using a procedure described elsewhere². For electrophysiological studies, 0.2 ml of the isolated cell suspension was placed on a depression slide and the cells were allowed to sediment for 5 min. Under Nomarski interference optics, cone horizontal cells were impaled with 30-50 MΩ KCl-filled micropipettes. The single-electrode clamp system (SEC) used for currentclamp of these cells is described in detail elsewhere^{6,7}. Briefly, the SEC switches a single microelectrode rapidly (3 kHz) between current-passing and voltage-recording modes. The technique allows for the passage of larger transmembrane currents, and for a more accurate measurement of the membrane potential during current passage, than is possible using standard Wheatstone bridge arrangements. Each cell was photographed before intracellular recording. Surface area measurements were determined by projecting an enlarged image of the cell onto graph paper. The cells were assumed to be flat disks with a thickness of 10-15 µm, which was estimated from the depth of focus.

The results shown here are based on intracellular recordings of >92 cone horizontal cells. Figure 1a is a photomicrograph of a cone horizontal cell from which an intracellular recording was

made. Cone horizontal cells are easily identified by two criteria: they are the largest cells in the retina^{2.8} and even in isolation, they still have the amoeboid shapes characteristic of horizontal cells in the intact retina and can be easily distinguished from other isolated cells^{2,8}. Figure 1b-d gives data on the passive membrane properties of the cell shown in Fig. 1a. The isolated cone horizontal cells used here usually had an amoeboid shape with numerous fine processes. We generally chose to impale the larger cells with the simplest morphology that could be clearly and unequivocally identified, but that were free of long processes. For the cell in Fig. 1a, 400-ms constant current pulses were applied and the resulting voltage transients recorded (see Fig. 1b). Figure 1c shows a plot of the steady-state voltage-current (V-I) relationship, obtained from transients such as those shown in Fig. 1b. In this particular cell, the V-I plot is linear over the voltage range -40 to +20 mV. However, few cells showed completely linear V-I plots over a wide voltage range. We typically measured a decrease in input resistance with large depolarizations or hyperpolarizations.

To calculate the specific membrane capacity of these cells, it was necessary to determine accurately the membrane time constant. Figure 1d shows the logarithm of the first derivative of two low-amplitude voltage transients (from Fig. 1b), one depolarizing and the other hyperpolarizing, plotted against time. The data points fit well to single exponentials with time constants of 17.3 and 18.2 ms, respectively. As we could detect only a single exponential in the low-amplitude voltage transients, the cell behaved as a single isopotential compartment, composed of a parallel resistor and capacitor. Moreover, the time constants calculated from the small depolarizing (10 mV) and hyperpolarizing (15 mV) transients are similar, which supports our assumption that the membrane resistivity is effectively ohmic in this narrow voltage range.

With the information from Fig. 1, the specific membrane properties of this cell can be calculated. The surface area (A) was estimated from Fig. 1a as $16,000 \mu m^2$. The input resistance (R_N) was $89.6 M\Omega$, and the average membrane time constant (τ_m) was

17.7 ms. These values yield a specific membrane resistivity (R_m) of 14,330 Ω cm² and a specific membrane capacity (C_m) of 1.2 μ F cm⁻².

In most cells, depolarizing current pulses revealed a regenerative voltage response as defined by an increasing positive slope in the membrane potential transient. An example of such a regenerative response is shown in Fig. 2. The resting membrane potentials of impaled cells from different preparations were quite variable, ranging from -10 to -100 mV. However, as most isolated cells in a given preparation had similar resting potentials, all with large input resistances, we believe that these variations in resting potentials are not the result of damage due to the microelectrode, but are most likely due to variations in the retinae used or in the isolation procedures. Cells with low resting potentials generally showed regenerative voltage responses if a steady hyperpolarizing current was applied before the depolarizing pulses. The hyperpolarization probably reduced delayed rectification and closed the voltage-dependent channels that are responsible for the regenerative response. The cell shown in Fig. 2 had a resting membrane potential of -25 mV, but the voltage transients were obtained when the cell was hyperpolarized to -65 mV. The passive properties of this cell were $R_N = 250 \,\mathrm{M}\Omega$ at $-25 \,\mathrm{mV}$, $A = 3.740 \,\mu\text{m}^2$, $R_m = 9.350 \,\Omega \,\text{cm}^2$, $r_m = 9.6 \,\text{ms}$ and $C_m = 9.6 \,\text{ms}$ $1.0 \, \mu \text{F cm}^{-2}$

The addition of tetrodotoxin (TTX, 10 µg ml⁻¹) to the bathing solution of these cells had no apparent effect on the regenerative responses. To test whether Ca2+ might be involved in the regenerative responses, we applied CoCl2, MnCl2 or NlCl2 by pressure injection to the bathing solution; all three of these divalent cations have been reported to block inward Ca2+ currents in various systems 10,11. We found a rapid and complete blockade of all regenerative voltage responses with the application of any one of these divalent cations at a final concentration of ~10 mM, although Ni²⁺ seemed to be the most effective. Figure 3a shows the regenerative voltage response from a cell bathed in $10 \mu g \text{ ml}^{-1}$ TTX. The transients in Fig. 3bwere taken a few minutes after applying 10 mM NI2+; the regenerative response could no longer be elicited. Similar results were obtained in six other cells. These experiments demonstrate that the regenerative voltage responses recorded in isolated cone horizontal cells are TTX-insensitive and probably Ca2+dependent.

The results from a number of isolated cells show that they have an average specific membrane capacity of $1.3\pm0.3~\mu F\ cm^{-2}$ (mean \pm s.d., n=7). A C_m of $1~\mu F\ cm^{-2}$ has been suggested to be a biological constant, as this value has been found for all carefully studied cells in both vertebrate and invertebrate nervous systems $^{12.13}$. Our results agree with this hypothesis. However, it should be emphasized that our data may have several sources of error. First, the sample of cells is limited and biased towards larger cells with the simplest morphologies. Second, the assumption of uniform thickness for each cell and the inaccuracy associated with measuring depth could increase our surface area estimate by 10-20%. Third, the measurement

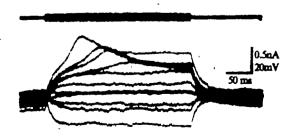

Fig. 2 Regenerative voltage responses from a cone horizontal cell. The resting potential of this cell was $-25\,\mathrm{mV}$. With the application of steady hyporpolarizing current, which brought the membrane potential to $-65\,\mathrm{mV}$, regenerative responses could be obtained in response to $300\mathrm{-ms}$ constant current pulses (top traces). The passive membrane properties of this cell, determined as described in Fig. 1 legend, were: $R_{\mathrm{H}} = 250\,\mathrm{M}\Omega$, $A = 3,740\,\mathrm{\mu m^2}$, $R_{\mathrm{H}} = 9,350\,\Omega\,\mathrm{cm^2}$, $r_{\mathrm{H}} = 9.6\,\mathrm{ms}$ and $C_{\mathrm{m}} = 1.0\,\mathrm{\mu F}\,\mathrm{cm}^{-8}$.

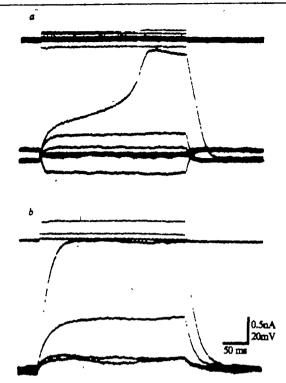

Fig. 3 Regenerative voltage responses blocked by Nl^{3+} . a, A regenerative voltage transient in response to a 300-ms constant current pulse. The resting potential of this cell was \sim -50 mV. Steady hyperpolarizing current brought the cell to \sim 90 mV, from which the pulses shown were given. The cell was bathed in 10 μ g mi⁻¹ TTX. b, The same cell several minutes after the application of 10 mM Nl^{3+} . No regenerative responses could be recorded with the cell at \sim 90 mV. Steady depolarizing and hyperpolarizing currents were passed to bring the cell to several different membrane potentials. The application of depolarizing current pulses from any of these different membrane potentials could not elicit a regenerative voltage response.

of the membrane time constant could be influenced by voltagedependent currents. This last source of error would be most critical in those cells with the largest specific membrane resistivities.

With the exception of an apparent lack of TTX-sensitive sodium channels, the active and passive membrane properties of cone horizontal cells seem to be similar to those described in various neurones from the central and peripheral nervous systems of both vertebrate and invertebrate species. Our results suggest that catfish cone horizontal cells, in isolation, can show regenerative behaviour that is probably Ca2+-dependent. The leak current in vivo, caused by the extensive electrotonic couplings among horizontal cells, might be expected to subtract from a voltage-dependent inward current and prevent the appearance of regenerative voltage responses. Accurate estimates of membrane resistivity are also difficult to make in the intact retina because of these electrical couplings between horizontal cells 14. For example, the input resistances of horizontal cells in intact retinae were reported to be of the order of 500 k Ω (ref. 14), a value about 200 times lower than that found in isolated horizontal cells. For these reasons, the ability to record from isolated cells is crucial for the study of the biophysical properties of these neurones.

Inhibition of basophil histamine release by anti-inflammatory steroids

Robert P. Schleimer, Lawrence M. Lichtenstein & Elizabeth Gillespie

Department of Medicine, Division of Clinical Immunology. Johns Hopkins University School of Medicine at The Good Samaritan Hospital, Baltimore, Maryland 21239, USA

The release of histamine from human leukocytes is a useful in vitro model for studying allergic disease1. Many of the drugs used in the treatment of allergy and asthma (for example, isoprenaline and theophylline) are effective inhibitors of in vitro histamine release². However, the anti-inflammatory steroids have not been found to inhibit the in vitro release of histamine from mast cells or basophils activated by immunological stimuli³⁻⁶. In view of the fact that the in vivo anti-allergic effects of steroids occur only 12-24 h after administration, we have re-examined the effects of these drugs on IgE-mediated histamine release from human basophils after prolonged incubations. We report here a time-dependent inhibition of histamine release from human basophils by glucocorticosteroids. The relative activity of a series of steroids as inhibitors of histamine release correlates well with the relative in vivo anti-inflammatory activity of the same compounds. These results suggest that the basophil may be an in vivo target of the anti-inflammatory steroids and that inhibition of this cell type may account for some of the activity of steroids in preventing inflammation.

Human leukocytes were prepared from the blood of normal volunteers by dextran sedimentation as described elsewhere⁸ except that sterile conditions were used. Cells were cultured in the presence or absence of steroids for up to 24 h, as described in Fig. 1 legend, after which they were washed and challenged with either anti-IgE or buffer control. Dexamethasone acetate, at concentrations up to 10⁻⁶ M, did not reduce the total cellular histamine content in incubations of 24 h. Total leukocyte viability, as assessed by Trypan blue exclusion, was always greater than 70% and usually greater than 80% after 24-h culture with or without up to 10^{-6} M dexamethasone acetate. In initial experiments, the drug in use was present during the wash and challenge procedures. However, it was determined that its omission during wash and challenge steps did not affect the extent of inhibition of histamine release, and it was therefore not included in most of the experiments described here.

The time course of onset of dexamethasone-induced inhibition of histamine release is shown in Fig. 1. Control release in the absence of steroid was 28%. Preincubation of cells with dexamethasone acetate for up to 2 h produced no inhibition of histamine release during the subsequent 45-min challenge. However, inhibition was noted after 4 h of incubation, and increased linearly for 24 h. Similar results were obtained with anti-IgE in three experiments. In 21 experiments using a 24-h incubation, histamine release in the control groups, stimulated with $0.1 \,\mu g \, ml^{-1}$ anti-IgE, was $34 \pm 3.3 \,\%$ (mean \pm s.e.m.) whereas that from cells exposed to $10^{-7} \, M$ dexamethasone acetate was $12.9 \pm 1.4\%$. In two experiments, using the cells of

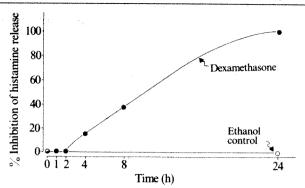

Fig. 1 Human leukocytes were collected from adult volunteers, sedimented in sterile dextran/EDTA, washed twice in sterile saline and cultured in 2-ml aliquots in multi-well tissue culture plates for 24 h in RPMI 1640 medium supplemented with penicillin/streptomycin, glutamine, 25 mM HEPES and 7% autologous serum. Dexamethasone acetate in ethanol at 10^{-2} M, or ethanol alone, was diluted in medium to a final concentration of 10added at various times so that total duration of exposure to the drug was as indicated. At the end of the culture period, cells were washed in PIPES-buffered saline, pH 7.3, containing 110 mM NaCl, 5 mM KCl and 25 mM PIPES, and resuspended in PIPESbuffered saline containing 1 mM CaCl₂ and 1 mM MgCl₂. Cells were then challenged with either 0.1 µg ml⁻¹ anti-IgE (a gift of Dr K. Ishizaka) or buffer control (spontaneous release) at 37 °C for 45 min. Histamine released into the supernatant was measured using an automated fluorometric technique²¹. Per cent histamine release was calculated as the fraction (×100) of total cellular histamine released into the challenge medium after subtraction of the spontaneous release (<5%). Per cent inhibition of histamine release was calculated as the reduction (expressed on a percentage basis) compared with control release induced by drug treatment.

ragweed-sensitive donors, histamine release stimulated by anti-IgE was inhibited by over 80% after a 24-h incubation with 10⁻⁷ M dexamethasone acetate.

To ascertain whether the in vitro activity of steroids parallels their in vivo effects, several steroids were tested for activity as inhibitors of basophil histamine release using 24-h incubation periods. The inhibition of histamine release by four antiinflammatory steroids showed a rank order of triamcinolone acetonide > dexamethasone acetate > 9α -fluorocortisone > hydrocortisone (Fig. 2). This order of potency is consistent with the anti-inflammatory potency of these compounds in man⁹, and the IC₅₀ of these and other steroids shown in Table 1 are similar to their binding constants for the steroid receptor 10,11. The sex steroids, β -oestradiol, testosterone and progesterone, as well as the cortisone metabolite, tetrahydrocortisone, were essentially inactive as inhibitors of histamine release. Prednisone, a cortisone analogue that is active in vivo, was inactive as an inhibitor of histamine release, whereas prednisolone, in two experiments, was an effective inhibitor with an approximate IC_{50} of 2.2×10^{-8} M. This observation is consistent with the hypothesis that prednisolone, the major metabolite of pred-

Table 1 Potency of various steroids as inhibitors of histamine release

Compound	IC ₅₀ (M)	n	Relative potency
Triamcinolone acetonide	3.1×10^{-9}	6	48
Dexamethasone acetate	7.8×10^{-9}	6	19
Prednisolone	2.2×10^{-8}	2	6.8
9α-Fluorocortisone	4.5×10^{-8}	4	3.3
Hydrocortisone	1.5×10^{-7}	8	1
Progesterone	$>10^{-5}$	1	< 0.01
β-Oestradiol	$>10^{-5}$	2	< 0.01
Testosterone	$>10^{-5}$	2	< 0.01
Prednisone	$>10^{-5}$	2	< 0.01
Tetrahydrocortisone	$> 10^{-5}$	3	< 0.01

IC₅₀, molar concentration of drug that inhibits histamine release by 50%, n, Number of experiments from which data are derived. Potency is relative to hydrocortisone.

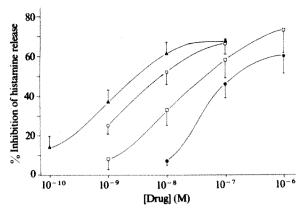

Fig. 2 Inhibition of basophil histamine release by triamcinolone acetonide (\triangle), dexamethasone acetate (\bigcirc), 9α -fluorocortisone (\square) and hydrocortisone (.). All steroids were dissolved in ethanol at 10-2 M and subsequently diluted in medium. Assay and calculations were performed as described in Fig. 1 legend and in the text. Data shown represent the mean ± s.e.m. inhibition of at least four experiments for each drug tested (see Table 1).

nisone, is responsible for the in vivo activity of prednisone 12,13. The relative and absolute potencies of the steroids tested are similar to their potencies as inhibitors of arachidonic acid release from guinea pig lung¹⁴ and transformed mouse fibroblasts¹⁵, as well as their potencies as inhibitors of lymphocyte mitogenosis 16 and macrophage plasminogen activator release¹⁷. Note that results similar to ours have recently been obtained using mouse peritoneal mast cells (M. Daëron, A. Sterk and T. Ishizaka, personal communication).

The mechanism of the steroid effect is unclear, but the observation that basophil activity is inhibited by glucocorticosteroids raises several important questions. First, it becomes necessary to determine to what extent a steroid-mediated inhibition of basophil activity plays a part in the abrogation of those delayedtype hypersensitivities which involve basophils 18,19. Second, as hydrocortisone inhibits histamine release at concentrations which are found naturally in the circulation, it becomes necessary to determine what role circulating glucocorticoids have in the regulation of basophil activity. Third, questions concerning the biochemical mechanism by which the steroids inhibit histamine release can be approached using a recent technique for obtaining human basophils at high purity20. Finally, it becomes necessary to ask what role the inhibition of basophil activity has in the glucocorticosteroid alleviation of allergic disease and asthma.

Lipoxygenase products modulate histamine release in human basophils

Stephen P. Peters, Marvin I. Siegel, Anne Kagey-Sobotka & Lawrence M. Lichtenstein

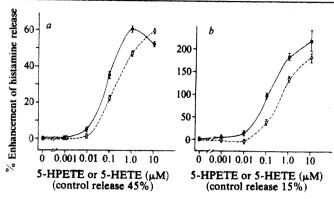

The Johns Hopkins University School of Medicine, Department of Medicine, Divisions of Clinical Immunology and Pulmonary Medicine, Baltimore, Maryland 21239 and Burroughs Wellcome Co., Research Triangle Park, North Carolina 27709, USA

Arachidonic acid released from cellular phospholipids is metabolized by two major enzyme systems1. The cyclooxygenase pathways are responsible for the production of prostaglandins, thromboxanes and prostacyclin while the lipoxygenase pathways form a series of monoperoxy- and monohydroxyeicosatetraenoic acids. The 5-lipoxygenase pathway eventually leads to the production of both leukotriene B, one of the most potent chemotactic molecules known, and SRS-A (slow-reacting substance of anaphylaxis-leukotrienes C and D). Our earlier studies of the lipoxygenase enzyme(s) suggested that a product(s) of lipoxygenase(s) is both necessary for histamine release from human basephils and blunts endogenous control mechanisms²⁻⁴. To test this hypothesis, we have studied the effect of exogenously added products of lipoxygenase pathways on antigen-induced histamine release from human basophilic leukocytes in vitro. The present report demonstrates that 5-hydroperoxyeicosatetraenoic acid (5-HPETE), at sub-micromolar concentrations, causes both a dose-dependent enhancement of histamine release and a reversal of the inhibition of histamine release caused by hormones and other agonists which act via adenylate cyclase. The reduced product of 5-HPETE, 5-hydroxyeicosatetraenoic acid (5-HETE) has both activities, but is approximately 3 to 10 times less potent.

As studies of the oxidation of arachidonic acid by cyclooxygenase and lipoxygenase pathways have been pursued, evidence has accumulated that products of the lipoxygenase pathways and other fatty acid hydroperoxides: (1) enhance anaphylactic mediator release from guinea pig lung^{5,6}, (2) are chemotactic for polymorphonuclear leukocytes^{7-1,4}, (3) can inhibit both leukotriene biosynthesis15 and platelet cyclooxygenase activity¹⁶, (4) enhance IgE-mediated release of histamine in rat mast cells¹⁷, (5) are incorporated into neutrophil phospholipids and triglycerides¹⁸ and induce degranulation of these cells¹⁹, and (6) may be involved in inflammatory and pyretic reactions in vivo²⁰

The nonspecific lipoxygenase inhibitor, 5,8,11,14-eicosatetraynoic acid, and 5,8,11-eicosatriynoic acid, a relatively specific lipoxygenase inhibitor, inhibit basophil histamine release caused by antigen-IgE interactions, C5a peptide, fMet peptides and the ionophore, A23187, in a complete and dose-dependent fashion^{2,3}. In addition, arachidonic acid and pharmacologic concentrations of indomethacin and other nonsteroidal anti-inflammatory drugs both potentiate histamine release and reverse the inhibition of histamine release caused by drugs and hormones that act via adenylate cyclase, while failing to affect the action of drugs which increase cyclic AMP levels by other mechanisms²⁻⁴. These data, together with the finding that the phospholipase A₂ inhibitor, p-bromophenacyl bromide, also causes a complete and dose-dependent inhibition of histamine release⁴, led to the hypothesis that a lipoxygenase product(s) of arachidonic acid, generated by phospholipase A2, was both obligatory for histamine release and negatively modulated the signal generated by receptors linked to adenylate cyclase.

Figure 1 shows the dose-response relationships for the enhancement of histamine release by 5-HPETE and 5-HETE. 5-HPETE had half-maximal effect at 0.10 µM, and a peak effect

Enhancement of basophil histamine release by 5-HPETE and 5-HETE. Peripheral blood leukocytes from atopic adult volunteers who had given informed consent were isolated by dextran sedimentation of venous blood anticoagulated with EDTA as previously described². The histamine release assay was performed in a total volume of 0.5 ml in buffer containing 25 mM PIPES, 110 mM NaCl, 5 mM KCl, 0.003% human serum albumin, 1.0 mM MgCl₂ and 1.0 mM CaCl₂. Incubations were carried out for 45 min at 37 °C after a 5-min preincubation of cells with drug or lipoxygenase product before addition of antigen, either ragweed antigen E or rye grass, group I. The lipoxygenase product, 5-HPETE, was prepared as described by Porter et al.²²; 5-HETE was prepared from 5-HPETE by reduction with NaBH4. These lipoxygenase products were added to 12×75-mm polypropylene reaction tubes as an ether solution which was evaporated under a stream of nitrogen immediately before use. Leukotrienes C and D were a gift from Dr Joseph Rokach of Merck, Sharp and Dohme and stored frozen as an aqueous solution at -70 °C. Dimaprit was a gift of Dr M. Parsons of Smith Kline and French. Histamine released was quantified by fluorometric assay as previously described^{23,24} and corrected for spontaneous release, typically <5% of the total histamine content. Experiments were carried out in duplicate or triplicate with cells from 3-10 atopic donors. None of the lipoxygenase products caused spontaneous histamine release. In the experiment above, assays were performed in triplicate with either 5-HPETE (1) or 5-HETE (1), Control histamine release was 45% (a) and 15% (b). Error bars indicate s.e.m.

at 1.0 µM. 5-HETE had a similar effect but was 60-80% as active as 5-HPETE in enhancing histamine release at a concentration of 1 µM. Examination of the linear portion of the enhancement dose-response curve shows that it requires 3 to 10 times more 5-HETE than 5-HPETE to cause an equivalent enhancement of histamine release. The enhancement observed is, of course, a function of the magnitude of the control histamine release. In a series of 20 experiments, the enhancement ranged from 15 to 60% when histamine release was 40-70% of total cellular histamine (Fig. 1a), and from 190 to 340% when histamine release was 10-15% of total cellular histamine (Fig. 1b). In a series of six experiments, 11-HPETE and 15-HPETE were 100 ± 40 times less active than 5-HPETE in enhancing release. The stable hydroperoxide, 13-hydroperoxylinoleic acid, showed no enhancement at this concentration in four of six experiments. In six experiments, other products of the 5-lipoxygenase pathway, leukotrienes C and D, at concentrations of 0.5-3 µM, caused no consistent enhancement (or inhibition) of antigen-induced histamine release. These results are in contrast to the observations of Schellenberg and co-workers, who showed differential effects for leukotriene C and D on 48/80-induced histamine release in rat mast cells²¹ Other lipoxygenase products, including the potent chemotactic molecule, leukotriene B¹²⁻¹⁴, were not available for evaluation.

Figure 2 demonstrates the previously reported specific reversal by indomethacin of the inhibition caused by the histamine type 2 agonist, dimaprit². The activity of 5-HPETE is essentially the same as that of indomethacin. 5-HETE also reversed the inhibition caused by dimaprit but to a lesser extent (data not shown). Similar reversal was seen in five of five experiments with 5-HPETE and four of five experiments with 5-HETE. In simul-

taneous experiments, neither indomethacin (as previously reported) nor 5-HPETE reversed the inhibition caused by dibutyryl cyclic AMP or isobutyl methylxanthine, agonists which increase cyclic AMP levels by mechanisms other than activation of adenylate cyclase (that is, directly or by phosphodiesterase inhibition). Thus, the effect of 5-HPETE in specifically reversing the inhibition of histamine release caused by agonists which act via adenylate cyclase is the same as that previously reported for indomethacin and arachidonic acid.

The mechanism by which antigen-IgE interactions cause mediator release from basophils and mast cells has been extensively studied^{2-4,17-19}. The bulk of the evidence suggests that stimulation of the basophil occurs by cross-linking cell-surface IgE molecules followed by phospholipase A2 activation leading to the production of arachidonic acid which is then metabolized by the lipoxygenase pathway(s) leading to histamine release. The present study provides direct evidence that specific 5lipoxygenase products (5-HPETE and 5-HETE) are able to modulate histamine release in human basophils; they can both enhance antigen-induced histamine release and specifically reverse the inhibition caused by agents that increase cyclic AMP levels via an effect on adenylate cyclase. Products of the 11- and 15-lipoxygenase pathways are much less active in this regard and leukotrienes C and D are inactive. The naturally occurring hydroperoxy derivatives of arachidonic acid are relatively unstable in aqueous solutions, being converted, usually within minutes, to the corresponding hydroxy compound. The present report demonstrates that both the relatively unstable 5-hydroperoxy derivative of arachidonic acid and the stable 5-hydroxyeicosatetraenoic acid have the ability to modulate histamine release in human basophils. Whether further metabolism of these compounds occurs during the in vitro incubation is unknown. Our interpretation assumes that exogenously added material will have a similar effect to endogenously generated products.

The mechanism by which lipoxygenase products enhance histamine release is unknown, although it is tempting to speculate that these products may be incorporated into membrane phospholipids and then induce degranulation, analogous to the mechanism proposed for human neutrophils^{18,19}. The ability of other lipoxygenase products to modulate enzymes involved in inflammatory reactions, including the inhibition of platelet cyclooxygenase activity¹⁶ and the inhibition of the biosynthesis of leukotrienes¹⁵, argues strongly for the importance of these compounds in inflammatory processes. Whether other lipoxygenase products, particularly leukotriene B, are capable of modulating histamine release in human basophils remains to be tested.

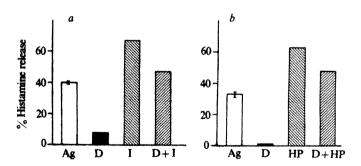

Fig. 2 Reversal of dimaprit inhibition of histamine release by indomethacin (a) and 5-HPETE (b). Cells were preincubated for 5 min with dimaprit (2 μM), indomethacin (2 μM), 5-HPETE (1 μM) or combinations of the above for 5 min before addition of antigen. Assays containing drug or lipoxygenase products were performed in duplicate; in general, replicate assays varied by <10%. Ag, antigen controls; D, dimaprit; I, indomethacin; HP, 5-HPETE. Error bars indicate range of histamine release for antigen controls.

Type-specific protective immunity evoked by synthetic peptide of Streptococcus pyogenes M protein

Edwin H. Beachey*†, Jerome M. Seyer‡, James B. Dale*, W. Andrew Simpson* & Andrew H. Kang*‡

The Veterans Administration Medical Center and the Departments of *Medicine, †Microbiology and ‡Biochemistry, University of Tennessee School of Medicine, Memphis, Tennessee 38104, USA

The M protein on the surface of Streptococcus pyogenes cells enables the organisms to resist ingestion and killing by phagocytic cells in the blood of the non-immune host. In the immune host, type-specific antibodies against the M protein neutralize the antiphagocytic effect and allow the rapid elimination of any invading streptococcci having the same serotype of M protein. Recent studies in our laboratories of the primary structure of one of these M proteins (type 24) have indicated that the molecule is composed of repeating covalent structures, each of which contains protective antigenic determinants. These results suggest that only a small portion of the M protein molecule may be required to produce primary protective immunity against \hat{S} . pyogenes. We now report that this notion is well founded. Our findings may have a bearing on the development of M-protein vaccines to protect against streptococcal infections causing acute rheumatic fever and rheumatic heart disease2.

The mechanism whereby streptococcal infections give rise to complications such as rheumatic fever remains a mystery³. Because the sera of some patients with rheumatic fever show serological cross-reactivity between heart tissue antigens and certain streptococcal antigens3, it has been feared that immunization with intact M-protein vaccines may lead to

rheumatic heart disease. However, we have recently found that rabbits and mice immunized with cyanogen bromide fragments (CB6 or CB7) of type 24 M protein containing only 35 amino acid residues each developed opsonic and protective antibodies against type 24 streptococci4. One of these peptides (CB7) has now been chemically synthesized (S-CB7) and we report here protective immunity in laboratory animals induced by S-CB7 covalently linked to polylysine. In addition, we present evidence that one of the protective determinants resides in a peptide fragment of CB7 containing only 12 amino acid residues.

The CB7 polypeptide fragment of type 24 M protein and a dodecapeptide starting at residue 18 and ending at residue 29 (S18-29CB7) were synthesized⁵ and purified by reverse-phase HPLC on Ultrasphere ODS2 (Whatman) columns (Penninsula laboratories). The S18-29CB7 peptide overlaps two subpeptides derived from trypsin digestion of lysyl-blocked CB7 (see below). Amino acid analyses confirmed the identity of the synthetic peptides. Automated Edman degradation 1,4 to the penultimate residue gave the amino acid sequence of S-CB7 as

> Asn-Phe-Ser-Thr-Ala-Asp-Ser-Ala-Lys-Ile-Lys-Thr-Leu-Glu-Ala-Glu-Lys-Ala-Ala-Leu-Ala-Ala-Arg-Lys-Ala-Asp-Leu-Glu-Lys-Ala-Leu-Glu-Gly-Ala-Met

This sequence is identical to that of the native CB7 fragment except that the COOH-terminal residue of S-CB7 is methionine, not homoserine4. The amino acid sequence of the S18-29CB7 peptide was found to be identical to the corresponding segment of CB7 except for the addition of a glycine tripeptide at the COOH terminal, which is used as a leash in the synthesis of the peptide (Penninsula Laboratories).

Three rabbits immunized with 25 nmol of S-CB7 emulsified in complete Freund's adjuvant (CFA)4 developed antibody titres at 6 weeks of 1:400, 1:1,280 and 1:25,600, respectively, as determined by enzyme-linked immunosorbent (ELISAs)2.6. However, only the serum showing the highest ELISA titre was capable of opsonizing type 24 streptococci (data not shown). Therefore, three additional rabbits were immunized with 25 nmol of CB7 covalently conjugated to polylysine (molecular weight (MW) =35,000) and emulsified in CFA. The sera of all three rabbits showed good antibody responses as measured by ELISAs or opsonic antibody assays (Fig. 1). In bactericidal assays (see Fig. 1 legend) using types 5, 6 and 24 streptococci, the immune sera were able to promote phagocytosis and killing of only the homologous type 24 streptococci, indicating that the humoral responses to the synthetic peptide fragment are type-specific.

Agar gel diffusion tests using the immune rabbit sera gave precipitin arcs between the polylysine conjugates of the synthetic and the native CB7, as well as with the intact pepsinextracted type 24 M protein (pep M24) molecule, which further confirms that the synthetic and native CB7 peptide fragments are immunochemically identical. Neither type 5 nor type 6 M protein was immunoreactive with anti-CB7 antiserum. None of the S-CB7 immune sera tested were reactive with frozen sections of human heart tissue assayed by immunofluorescence as previously described2.

To demonstrate the protective capacity of the antisera against S-CB7, mice were passively immunized with a pool of the immune rabbit sera and challenged after 24 h with live type 24 or type 6 streptococci. The results (Table 1) clearly show the type-specific protective capacity of the immune sera and indicate that the S-CB7 peptide contains at least one protective antigenic determinant of type 24 streptococci.

To determine whether protective antigenic determinants resided in yet smaller peptide fragments, the CB7 peptide was cleaved at its arginine residue by trypsin, after blocking lysyl residues with recrystallized maleic anhydride (to a molar excess

of 20 over the total number of lysyl residues)4,7 After digestion with trypsin (TPCK (tosyl-phenylethyl-chloromethyl-ketone) -treated, Worthington) at an enzyme/substrate ratio of 1:50 (w/w) in 0.05 M NH₄HCO₃, pH 8.3, the lysyl residues were demaleylated using pyridine/acetate (1:10), pH 3.0 at 60 °C for 6 h. The demaleyated peptides were then HPLC-separated on a column of Ultrasphere ODS2 equilibrated with 0.01 M phosphate buffer, pH 7.2, and eluted on a gradient of 0-40% acetonitrile8. In this way, a 12-residue COOH-terminal and a 23-residue NH₂-terminal peptide were purified and then tested for their ability to inhibit opsonic antibodies4 (see Fig. 1 legend). For 50% inhibition of opsonization of type 24 streptococci. 9 nmol of the 23-residue, NH₂-terminal peptide and 20 nmol of the 12-residue, COOH-terminal peptide of CB7 were needed. compared with only 1.6 nmol of a mixture of the two peptides and 0.8 nmol of the uncleaved CB7 peptide. The greater activity

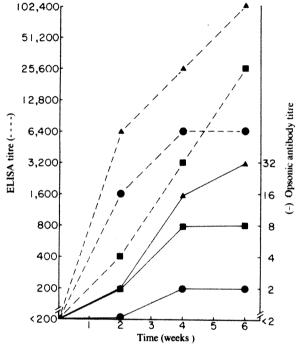

Fig. 1 Immune responses in three rabbits (△, ■, ●) as measured by ELISAs (---) or opsonic antibody (- assavs after immunization with 24 nmol of S-CB7 conjugated to polylysine and emulsified in complete Freund's adjuvant (CFA) followed a week later by the same dose emulsified in CFA. Each symbol represents a different rabbit (see also Table 1 legend). Sera collected at 2-week intervals were assayed for antibodies to type 24 M protein adsorbed to the walls of plastic cuvettes by the ELISA method as previously described^{2,6}, except that semi-automatic methods were used (EIA PR50 automatic analyser and injector, Gilford). ELISA titres are expressed as the reciprocal of the highest dilution of serum giving an absorption >0.1 at 405 nm. Opsonic antibodies were assayed as described elsewhere¹. Briefly, the test mixture consisted of 0.4 ml of fresh heparinized (10 U ml⁻¹) human blood, 0.05 ml of a standard suspension of streptococci and 0.05 ml of various dilutions of test serum. The number of streptococcal units per leukocyte was ~10. The percentage of neutrophilic leukocytes counted that ingested one or more bacteria was estimated by microscopic examination of stained smears prepared from a drop of test mixture after incubation for 30 min. The opsonic antibody titres are expressed as the reciprocal of the highest twofold dilution of test serum in three separate tests that promoted phagocytosis of streptococci in ≥10% of the neutrophils counted after incubation at 37 °C for 30 min; the same organisms in the presence of preimmune rabbit serum were phagocytosed by ≤2% of neutrophils in each test. Antisera giving titres >1:4 all produced phagocytosis in the range 40-70% when undiluted. The results of these phagocytosis tests were confirmed by indirect bactericidal tests performed as previously described¹⁸. Type specificity of the sera was confirmed by the failure of the S-CB7 immune sera to promote phagocytosis and killing of heterologous type 5 and type 6 streptococci.

Table 1 Protection of mice against challenge infections with type 24 streptococci by sera of rabbits immunized with S-CB7

	LD ₅₀ in mice challenged with:			
Serum used to immunize mice passively	Type 6 streptococci	Type 24 streptococci		
Preimmune serum Pooled (three rabbits) immune anti-S-CB7 serum	<500 (2/15) <500 (2/15)	<500 (3/15) 3,500,000 (14/15)		

Three rabbits were immunized intracutaneously with 25 nmol of S-CB7 conjugated to polylysine (MW \approx 35,00) and emulsified in CFA as previously described⁴. The initial immunizing dose was followed 1 week later by the same dose emulsified in incomplete Freund's adjuvant and injected subcutaneously. Preimmune and immune sera, obtained before immunization and 6 weeks after the initial immunizing dose, respectively, were pooled and white Swiss mice injected intraperitoneally with 0.2 ml of either serum. The mice were challenged 24 h later by the same route with various doses $500-4 \times 10^6$ colony-forming units of type 6 or type 24 streptococci. The survivals were recorded over a 7-day period and are shown in parentheses as the number of survivors per number of challenged mice.

of the mixture of the two peptide fragments of CB7 indicates that CB7 contains at least two distinct type-specific protective determinants, and that one of these resides in a peptide containing only 12 amino acid residues. The synthetic dodecapeptide overlapping these two peptides (residues 18–29) had no opsonic inhibitory effect in doses as high as 100 nmol, suggesting that neither immunodeterminant is included in this dodecapeptide. However, the possibility that the COOH-terminal triglycine residues may interfere with antibody binding at that end of the dodecapeptide has not been excluded.

In contrast to the type specificity of the humoral immune responses to S-CB7, the cellular immune responses were highly cross-reactive. The lymphocytes of S-CB7-immunized rabbits were equally responsive to a heterologous type 5 M protein and an homologous type 24 M protein (Table 2). Moreover, immunization of rabbits with the synthetic dodecapeptide (S18-29CB7), although not providing effective humoral immunity, induced cellular immunity to both serotypes of M protein similar to that seen after immunization with S-CB7 (Table 2). The lymphocytes from none of the animals responded to S-CB7 or S18-29CB7, indicating that these peptides were of insufficient molecular size to elicit the *in vitro* blastogenic response of sensitized lymphocytes.

Recently Audibert et al. 10 actively immunized laboratory animals against diptheria toxin using a chemically synthesized oligopeptide. However, we believe that our results are the first to show that a synthetic polypeptide antigen can raise antibodies which promote phagocytosis and killing of a bacterial pathogen. The synthetic CB7 of type 24 streptococcal M protein represents a 35-amino acid fragment of the parent molecule, which consists of 376 amino acid residues¹. The molecule has previously been shown to consist of repeating covalent structures, the first 20 residues of CB7 being indentical to the corresponding regions of four other peptide fragments (CB3, CB4, CB5 and CB6)¹. Two additional fragments (CB1 and CB2), each with a MW of ~10,000, have NH₂-terminal amino acid sequences which are different from the smaller peptide fragments but are identical to each other and to the intact pepsin-extracted M protein (pep M24) molecule for at least the first 27 residues^{1,1}

In addition, the 12 COOH-terminal residues of CB1 and CB2 were found to be identical to those of each of the smaller peptides (unpublished data). It was particularly intriguing that one of the protective determinants was shown to reside in this 12-residue peptide, which is repeated seven times in the pep M24 molecule. Because of the repetitive nature of the primary structure of the M protein molecule it is not surprising that antibody directed against such a small segment of the molecule proved to be opsonic and presumably protective. The repetition of the determinant would provide multiple sites of interaction

Table 2 Blastogenic responses of lymphocytes from rabbits immunized with S-CB7 or S18-29CB7 fragments of type 24 M protein

		Mean c.p.m. (±s.e.m.) of lymphocytes cultured with:				
Rabbit	Immunizing antigen	Control	M5	M24		
8026 8027 8028	S-CB7 S-CB7 S-CB7	98 ± 23 181 ± 28 156 ± 31	$3,743 \pm 411$ $12,684 \pm 1,454$ $43,391 \pm 3,094$	4,721±479 829±124 36,449±5,416		
7919 7921 8020	S18-29CB7 S18-29CB7 S18-29CB7	415 ± 27 135 ± 31 705 ± 59	$11,521 \pm 3,081$ $17,056 \pm 3,081$ $12,487 \pm 918$	$12,038 \pm 243$ $3,575 \pm 1,265$ $4,916 \pm 362$		
8007 8008	CFA (control) CFA (control)	76 ± 102 31 ± 11	64 ± 12 153 ± 25	40 ± 2 83 ± 25		

Heparinized (100 U ml⁻¹) peripheral blood was obtained from rabbits 2-6 weeks after immunization (see Table 1 legend) by cardiac puncture. Mononuclear cells were isolated by Ficoll-Hypaque gradient centrifugation as described elsewhere ^{17,19}. Lymphocytes were washed three times and resuspended in RPMI 1640 (Gibco) supplemented with penicillin (100 U ml⁻¹), streptomycin (100 µg ml⁻¹), L-glutamine (2 mM) and HEPES buffer (25 mM). Lymphocytes (2 × 10⁵) were incubated at 37 °C with 50 µg per culture of each antigen tested in 96-well microculture plates (Falcon Plastics) in a total volume of 200 µl supplemented with 5% heat-inactivated fetal calf serum. Control cultures were incubated in the same volume of medium without antigen. Eighteen hours before collecting, 1 μCi of ³H-thymidine (specific activity 2 Ci mmol⁻¹, Research Products International) in 25 μl culture medium was added to each well. All cultures were collected after 5 days using multiple automated sample harvester and the cells assayed for radioactivity in a liquid scintillation counter as described elsewhere 17.20. CFA, complete Freund's adjuvant. Control animals were injected with the same volume of CFA emulsified in 0.15 M NaCl without antigen.

with the immunoglobulin molecules. Such interaction at multiple sites seems to be necessary for optimal opsonization of M protein-containing streptococcal cells^{†2}.

The significance of the cell-mediated cross-reactions between synthetic peptide fragments and heterologous M proteins is unclear; structural similarities between the M proteins 11,13-16 may account for these cross-reactions as well as for the high degree of cellular immunity to various M proteins recently observed in lymphocytes from human adults as well as cord blood of newborn infants¹

The immunogenicity of small peptide fragments is encouraging for the development of safe and effective vaccines against those streptococcal infections that initiate rheumatic fever and rheumatic heart disease2. The efficacy of very small peptides would permit disposal of a large portion of the M protein molecule and, therefore, should reduce the chances of eliciting immunological cross-reactions against host tissues. Thus, the continued identification of peptide structures responsible for protective immunity should yield a pool of small peptides that may eventually be synthesized and administered safely to humans as vaccine broadly protective against many serotypes of streptococci, particularly against those strains that trigger post-streptococcal sequelae.

Binding of MLR precursors requires immunosorbents which present both self- and alloantigen

Heather Y. Schnagl & William Boyle

Department of Microbiology, University of Melbourne, Parkville, Victoria 3052, Australia

The response of T lymphocytes to antigens of the major histocompatibility complex (MHC) in a species is commonly measured by two assays. The mixed lymphocyte reaction (MLR) measures proliferating lymphocytes (Tp), and cell-mediated cytolysis (CMC) measures the cytotoxic T cells (T_c) generated, which can destroy tissue cells bearing the alloantigens against which the response is directed1. Tp and Tc are thought to be derived from different precursors, the Tp-P and Te-P respectively, and each seem to have different requirements for activation. Initially it was claimed that Tp-P and Tc-P were coded to respond to antigens specified by different genes in the MHC2 but this distinction has since been shown not to be absolute³⁻⁶. We previously demonstrated that Tp-P and Tc-P had different antigen-binding characteristics as T.-P could be bound in a haplotype-specific manner to allogeneis monolayers but $T_{\mathfrak{p}}\text{-}P$ were not bound in these conditions. We report here further experiments which show that these two populations have qualitatively distinct antigen recognition properties, by demonstrating that Tp-P will bind only when self- plus alloantigen are presented by a monolayer, whereas Tc-P will bind when alloantigen alone is present.

Our original observation that monolayers of preincubated spleen cells specifically absorbed cytotoxic precursors, Tc-P, but failed to bind precursors of proliferative cells, T_p-P, has been confirmed in many experiments. Because the proliferative response seen in MLR reactions had been shown to be strongest when stimulated by H-2I region antigens, it seemed possible that T_p-P did not bind because monolayers of spleen cells were used and not all these cells expressed Ia determinants. Poly-Llysine monolayers of B-lymphocyte blasts were therefore prepared from B10 mice, then spleen cells from B10.BR mice incubated on these for 1 h. The nonadherent cells were recovered and cultured for MLR and CMC production against X-irradiated B10 and B10.D2 cells. Table 1 shows that the results were the same as those obtained with spleen cell monolayers; T_c-P were bound but not T_p-P. Similar experiments

Table 1 Absorption on B-cell blast monolayers and its effect on the proliferative and cytotoxic response of the nonadherent B10.BR responder population to stimulation with X-irradiated B10 spleen cells

Responder	Absorbing LPS blast monolayer	Stimulator	Proliferative Response (c.p.m. ³ H-T)	Cytoto H-2 ^b target	xic titre H-2 ^d target

B10.BR	B 10	X-B10.BR	500 ± 50		
X-B10.BR	B10	X-B10	230 ± 20		
X-B10.BR	B 10	X-B10.D2	130 ± 10		

B10 spleen cells (3×10⁸) were cultured in 75 cm² flasks (Falcon no. 3024) in a final volume of 75 ml of Eagle's minimum essential medium plus non-essential amino acids, supplemented with 10% v/v fetal calf serum (FCS) and 7×10^{-5} M 2-mercaptoethanol (MEM/FCS) containing $10\,\mu\mathrm{g}\,\mathrm{ml}^{-1}$ of lipopolysaccharide (LPS, Difco no. 3122-25) at 37 °C with 10% CO₂ in air for 3 days to generate B-cell blasts. After washing, $1-2\times10^7$ blast cells were attached to poly-L-lysine-coated dishes as described previously. B10.BR responder spleen cells, or in one case X-irradiated B10.BR (X-B10.BR) spleen cells as controls, were absorbed on the resultant monolayers as previously described. Briefly, B10.BR responder spleen cells (2×10^7) in 2 ml MEM/FCS were added to each monolayer. The dishes were centrifuged at 100g for 5 min then incubated at 37 °C with 10% CO2 in air for 1 h. The nonadherent B10.BR responder cells were recovered by brief agitation, washed once, and 2×10^7 were resuspended in 8 ml MEM/FCS and divided equally between two 25 cm² flasks (Falcon no. 3013). Control cultures containing 107 unfractionated B10.BR spleen cells in 4 ml MEM/FCS were similarly prepared. To each flask were added 107 X-irradiated (1,000 rad) stimulator spleen cells in 1 ml. Stimulator cells of the monolayer strain (X-B10, H-2b) were added to one of each pair of flasks representing the nonadherent population from a single dish, while stimulators of an unrelated strain (X-B10.D2, H-2d) or of the responder strain (X-B10.BR) were added to the remaining flask. All cultures were prepared in duplicate and incubated upright at 37 °C with 10% CO₂ in air for 5 days. To determine the proliferative response, duplicate 0.3-ml samples of each culture after 3 days incubation were transferred to a microtitre tray (Sterilin no. M29 ARTL). After centrifugation at 100g for 5 min, half the supernatant was discarded and 25 µl of medium containing 0.5 µCi of ³H-thymidine (³H-T) were added to each well. After incubation in a humidified box with 10% CO2 in air for 18 h, cultures were transferred to microtubes and treated according to the method of Smart et al. 16. Results obtained were expressed as c.p.m. 3H-T and represent the mean ±s.d. of quadruplicate determinations. Cytotoxicity was determined after 5 days incubation using a microassay described elsewhere¹⁷. Duplicate cultures were pooled, washed and resuspended in 0.3 ml RPMI 1640 supplemented with 10% v/v FCS (RPMI/FCS). All T_c populations were titrated against ⁵¹Cr-labelled tumour target cells of both stimulator haplotypes. The results obtained were expressed as % lysis ±s.d. of triplicate determinations. Per cent specific lysis represents the % lysis minus the spontaneous release of label by target cells incubated with medium alone. The cytotoxic titre for a given Te population was alculated as the reciprocal of the highest dilution of the Te population which gave 15% specific lysis of the target concerned.

using mouse embryonic fibroblasts which have also been shown to express I-region antigens^{8,9} also failed to show depletion of T_p-P .

Although T-cell responses to MHC alloantigens have always been considered not to require self-antigen presentation, in the absence of any other effective system for binding T_p-P, we examined the effect of using absorbent monolayers which copresented both allo- and self-antigen. Table 2 shows the results of absorbing B10.BR spleen cells separately on to monolayers composed of preincubated splenic lymphocytes of B10.BR, BALB/c or (B10.BR×BALB/c)F₁ hybrid origin. Neither the B10.BR nor BALB/c monolayers bound T_p-P, as shown by the unimpaired MLR response of the nonadherent B10.BR cells when stimulated with X-irradiated BALB/c or B10 cells. The BALB/c monolayers were adequate as shown by the fact that, although T_p-P were not bound, T_c-P directed against BALB/c were bound (data not shown). However, B10.BR cells which had been exposed to the (B10.BR×BALB/c)F₁ monolayer were found to be depleted of both T_c-P and T_p-P when stimulated by BALB/c alloantigens. The T_p-P depletion was apparently specific as the T_p response to B10 alloantigens was unimpaired.

To ensure that the reduction in ability to respond to BALB/c antigens by the B10.BR cells, which were nonadherent to the $(B10.BR \times BALB/c)F_1$ monolayer, was due to binding of T_p -P and not to induction of a suppressor effect, non-F1 monolayer-

adherent B10.BR cells were added to normal B10.BR spleen cells and stimulated with X-irradiated BALB/c cells. As can be seen in Table 3, no evidence was found for suppression by the B10.BR cells that were nonadherent to the F_1 monolayer. An alternative explanation of the results is that T_p-P were either bound or inactivated nonspecifically by exposure to the F monolayer and that the apparent specificity of the undiminished anti-B10 response was attributable to F, monolayer cells which were mounting an anti-B10 response. However, this was not the case as the cells which incorporated ³H-T on stimulation by B10 alloantigens were susceptible to complement-mediated lysis with anti-B10.BR serum but not with anti-BALB/c serum (Table 4). It was therefore concluded that the reduction in proliferation was due to binding of the T_p-P to the F₁ monolayer.

The specificity of T_p-P depletion was confirmed and investigated further by exposing B10.BR spleen cells to monolayers of B10.BR, BALB/c, B10, (B10.BR×BALB/c)F₁, $(B10.BR \times B10)F_1$ or $(B10 \times BALB/c)F_1$ spleen cells. The results are summarized in Table 5. Absorption of anti-BALB/c T_p -P occurred only on (B10.BR × BALB/c) F_1 monolayers. The depletion is specific for the anti-BALB/c response as the nonadherent B10.BR cells gave an undiminished MLR response to B10 alloantigen stimulation. The specificity of the depletion technique is further illustrated by the demonstration that absorption on a (B10.BR × B10)F₁ monolayer depleted the anti-B10 proliferative response but not the anti-BALB/c response. This experiment also defines further the self requirement, because B10.BR were not depleted of anti-BALB/c T_p-P when exposed to a monolayer of (B10× BALB/c)F₁, indicating that the self-antigen recognized must be coded in the H-2 region. This has been confirmed by further experiments (data not shown) in which B10 responder cells

Table 2 Absorption of B10.BR responders on preincubated (B10.BR× BALB/c)F₁ monolayers specifically depletes the proliferative response of the nonadherent responder population to stimulation with X-irradiated BALB/c spleen cells

Responder	Absorbing monolayer	Stimulator	Proliferative response (c.p.m. ³ H-T)
B10.BR		X-BALB/c	$6,560 \pm 480$
B10.BR		X-B10	$5,310 \pm 510$
B10.BR	****	X-B10.BR	500 ± 80
B10.BR	B10.BR	X-BALB/c	$6,710 \pm 310$
B10.BR	B10.BR	X-B10	$5,450 \pm 470$
B10.BR	B10.BR	X-B10.BR	510 ± 50
B10.BR	BALB/c	X-BALB/c	7.890 ± 960
B10.BR	BALB/c	X-B10	$6,420 \pm 400$
B10.BR	BALB/c	X-B10.BR	510 ± 60
B10.BR	$(B10.BR \times BALB/c)F_1$	X-BALB/c	310 ± 120
B10.BR	$(B10.BR \times BALB/c)F_1$	X-B10	$5,850 \pm 610$
B10.BR	$(B10.BR \times BALB/c)F_1$	X-B10.BR	390 ± 40

B10.BR responder spleen cells were absorbed onto B10.BR, BALB/c (H-2d) or (B10.BR × BALB/c)F₁ spleen cell monolayers (preincubated for 4 h) as described in Table 1. The resulting nonadherent responder cells were stimulated with X-irradiated BALB/c (X-BALB/c), B10 (X-B10) or B10.BR (X-B10.BR) spleen cells. After 3 days incubation the proliferative response was determined as described in Table 1 legend.

Table 3 Inability of B10.BR responders nonadherent to (B10.BR×BALB/c)F₁ preincubated monolayers to suppress the proliferative response of normal, unfractionated B10.BR responders to stimulation with X-irradiated BALB/c

	Responder popul	ation	
B10.BR	X-B10.BR	B10.BR nonadherent to F ₁ * monolayer	Proliferative response (c.p.m. ³ H-T)
$\begin{array}{c} 5 \times 10^6 \\ 5 \times 10^6 \end{array}$	5×10 ⁶	5×10 ⁶	$2,930 \pm 250$ $2,780 \pm 110$
	5×10^{6}	5×10^{6}	230 ± 70

B10.BR responder cells nonadherent to a (B10.BR × BALB/c)F; monolayer (5×10^6) were mixed with an equal number of unfractionated B10.BR spleen cells. These were stimulated with 10^7 X-irradiated BALB/c spleen cells as were control cultures containing 5×106 unfractionated B10.BR responder spleen cells and 5×10^6 X-irradiated B10.BR spleen cells. * $F_1 = (B10.BR \times BALB/c)F_1$.

could be depleted of anti-BALB/c Tp-P by exposure to a (B10×BALB/c)F₁ spleen monolayer but not a (B10.BR× BALB/c)F₁ monolayer.

The specificity of binding of T_n-P by monolayers presenting self-plus alloantigen has been tested using a number of parental and F₁ strains. These have confirmed the general observation that T_p-P were bound only when the responder and absorbing F₁ monolayer shared a common haplotype, and the depletion was specific for the haplotype of the other parent. In addition, we have found that monolayers composed of mixtures of responder and stimulator spleen cells would not absorb anti-stimulator T_p-P. The level of depletion achieved by absorption on semiallogeneic F₁ monolayers has varied for different combinations of responder-monolayer mouse strains but has been consistent for any single combination. This is not surprising as we found that even for T_c-P binding, the level of depletion depends on the time of preincubation before the monolayer is constructed and this differs from strain to strain. All the experiments reported here using F₁ cells have involved only a 4-h preincubation which may not be optimal for all combinations.

Table 4 Proliferative response of the B10.BR nonadherent population to stimulation by X-irradiated B10 is not due to detached (B10.BR×BALB/c)F1 monolayer cells

	Preincubated	Co.	Total	Proliferative response (c.p.m. ³ H-T)
Responder	monolayer	Stimulator	Treatment	(c.p.m. ri-1)
B10.BR		X-B10	C' only	$4,980 \pm 220$
B10.BR		X-B10	Anti-BALB/c+C'	$4,560 \pm 190$
B10.BR		X-B10	Anti-B10.BR+C'	$2,280 \pm 90$
F,*		X-B10	C' only	$6,680 \pm 290$
F,		X-B10	Anti-BALB/c+C'	$3,050 \pm 120$
F,		X-B10	Anti-B10.BR+C'	$3,100 \pm 110$
B10.BR	F ₁	X-B10	C' only	$4,380 \pm 210$
B10.BR	\mathbf{F}_{1}	X-B10	Anti-BALB/c+C'	$4,550 \pm 180$

B10.BR, (B10.BR \times BALB/c)F $_1$ or B10.BR responders that were nonadherent to preincubated (B10.BR \times BALB/c)F $_1$ monolayers were stimulated with Xirradiated B10 (X-B10) spleen cells. Samples of 3-day cultures were incubated with 3H-T as described in Table 1 legend. After labelling, replicate samples were pooled, washed and resuspended in 0.2 ml RPMI/FCS. To three 50-µl aliquots the following were added: (1) 50 µl of RPMI/FCS; (2) 50 µl of a 1:4 dilution of B10.BR anti-BALB/c serum; (3) 50 µl of a 1:4 dilution of a BALB/c anti-B10.BR serum. After incubation for 30 min the tubes were centrifuged and supernatants discarded; 0.2 ml of a 1:8 dilution of rabbit complement (C') was added to each tube and incubated for a further 30 min. After washing twice in RPMI/FCS the samples were collected and processed as described in Table 1

B10.BR	$(B10.BR \times B10)F_1$	X-B10	900 ± 110
B10.BR	$(B10 \times BALB/c)F_1$	X-BALB/c	$10,370 \pm 520$
B10.BR	$(B10 \times BALB/c)F_1$	X-B10	$20,640 \pm 1,020$

B10.BR responder spleen cells were absorbed, as described in Table 1 legend, on monolayers of B10.BR, BALB/c, B10, (B10.BR \times BALB/c) F_1 , (B10.BR \times B10)F₁, or (B10 × BALB/c)F₁ spleen cell monolayers that had been preincubated for 4 h. The resultant nonadherent responder cells were stimulated with Xirradiated BALB/c, B10 or B10.BR spleen cells. After 3 days incubation the proliferative response was determined as described in Table 1 legend. The results are expressed as c.p.m. minus control values (stimulated with X-B10.BR).

The importance of the experiments reported here is that, in addition to clarifying the distinction between antigen recognition by T_p-P and T_c-P, they present the first evidence of the need for self-antigen recognition by T cells coded to respond to alloantigens of the MHC. It is already well established that T cells responsive to non-MHC antigens require the extraneous antigen to be presented together with self-antigens 10-15. This distinction has been the basis of suggestions that alloreactive cells might, in fact, include multiple clones coded to self plus various extraneous antigens. This view will require some revision if the need for self-plus alloantigen demonstrated here is found to be generally applicable to the activation of cells which proliferate in response to MHC alloantigens. It should be stressed that in our experiments we have measured binding of precursors, not activation, but preliminary tests suggest that the same features apply to activation.

Adrenaline activation of phosphofructokinase in rat heart mediated by α -receptor mechanism independent of cyclic AMP

M. G. Clark & G. S. Patten

Commonwealth Scientific and Industrial Research Organization, Division of Human Nutrition, Kintore Avenue, Adelaide, South Australia 5000, Australia

We recently reported that adrenaline treatment of the perfused rat heart produced a marked activation of phosphofructokinase when assayed at low substrate concentration using a new isotopic assay2. As muscle phosphofructokinase has been reported to be phosphorylated by the cyclic AMP-dependent protein kinase3, activation of phosphofructokinase might be expected to result from phosphorylation mediated by the β -receptor/adenylate cyclase/cyclic AMP-dependent protein kinase sequence. We now report that this is not so, but that activation of phosphofructokinase in the perfused rat heart occurs independently of phosphorylase activation, by a cyclic AMP-independent mechanism, and that this process seems to be mediated predominantly through the α -adrenergic receptors. We believe this represents the first example showing that not only in liver 4.5 but also in a muscular tissue, occupancy of an α -adrenergic receptor changes the activity of a glycolytic enzyme. In addition, the present findings imply a coordination of muscle glycolysis with hepatic glucose output.

Figure 1 shows the effect of varying ATP concentration on extract phosphofructokinase activity from control and adrenaline-treated hearts. The adrenaline-activated form of the enzyme as expressed in crude heart extracts displays higher activity than the control form at all ATP concentrations. This is most pronounced at ATP concentrations > 0.5 mM, where the control form is almost totally inhibited. We have subsequently used this difference in sensitivity to inhibition by ATP to define an 'activity ratio' for phosphofructokinase where the control (unactivated) form of the enzyme is 0.2 ± 0.1 and the activated form of the enzyme is 0.6 ± 0.1 , representing the activity of phosphofructokinase determined at 1 mM ATP divided by that at 0.1 mM ATP (both at 0.01 mM hexose 6-phosphate).

Table 1 shows the effect of 5-min perfusions with adrenergic agonists or antagonists on the activity ratios of phosphofructokinase and glycogen phosphorylase in heart. For phosphofructokinase the basal activity ratio of 0.21 was increased about threefold by both adrenaline $(10^{-5} \, \mathrm{M})$ and $10^{-5} \, \mathrm{M}$ phenylephrine and remained elevated following gel filtration of the heart extracts (results not shown). Neither $10^{-5} \, \mathrm{M}$ isoprenaline nor $10^{-5} \, \mathrm{M}$ phenoxybenzamine had any effect, but $10^{-5} \, \mathrm{M}$ propranolol increased the ratio to 0.35. As the increase produced by adrenaline was blocked by phenoxybenzamine but not by propranolol, it was concluded that activation of phosphofructokinase was mediated predominantly through the α -receptor. This view was further supported by the observation that the marked increase in phosphofructokinase activity ratio produced by $10^{-5} \, \mathrm{M}$ phenylephrine was also blocked by $10^{-5} \, \mathrm{M}$ phenoxybenzamine.

In contrast to a predominantly α -receptor-mediated activation of phosphofructokinase, the activation of phosphorylase was mediated by a β -receptor mechanism. Adrenaline $(10^{-5} \, \mathrm{M})$ and $5 \times 10^{-7} \, \mathrm{M}$) and $10^{-5} \, \mathrm{M}$ isoprenaline each increased the phosphorylase activity ratio (a/a+b) approximately fourfold. $10^{-5} \, \mathrm{M}$ Phenylephrine had a marginal effect. Neither $10^{-5} \, \mathrm{M}$ propranolol nor $10^{-5} \, \mathrm{M}$ phenoxybenzamine had any stimulatory effect. The increases produced by adrenaline and isoprenaline were totally blocked by the β -antagonist, propanolol $(10^{-5} \, \mathrm{M})$, but the adrenaline-mediated increase in phosphorylase activity ratio remained unaffected by the α -antagonist, phenoxybenzamine $(10^{-5} \, \mathrm{M})$.

The marginal increase in phosphorylase activity ratio produced by the highest concentration of phenylephrine (10^{-5} M) was blocked by 10^{-5} M phenoxybenzamine. However, lower concentrations of phenylephrine ($\leq 10^{-6} \text{ M}$) significantly increased the activity ratio of phosphofructokinase but did not increase that of phosphorylase (Table 1).

Figure 2 shows the time course effects of 10^{-5} M isoprenaline, 10^{-5} M phenylephrine and 10^{-5} M naphazoline on the activity ratios of phosphofructokinase and phosphorylase as well as the

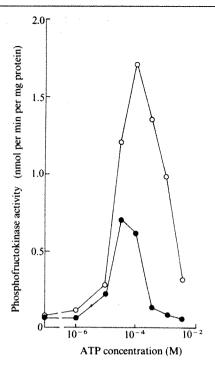

Fig. 1 Effect of ATP concentration on phosphofructokinase activity in extracts from control (and adrenaline-treated () hearts. Hearts of adult male hooded Wistar rats (200-250 g) that had been fed ad libitum on a standard diet were perfused in the Langendorff manner11. The perfusion medium contained 118 mM NaCl, 4.8 mM KCl, 1.2 mM MgSO₄, 1.2 mM phosphate, 25 mM NaHCO₃, 3.0 mM CaCl₂ and 0.5 mM Na₂EDTA and was equilibrated with $O_2 + CO_2$ (95 + 5) to give a pH and pO₂ of 7.4 and 450 mm Hg, respectively. After a 10-min non-recirculating perfusion (pressure 60 mm Hg, temperature 37 °C) the hearts were perfused in a recirculating manner with identical medium containing hormone or saline. After the appropriate time of perfusion (in this case 5 min) the hearts were freezeclamped using tongs that had been precooled in liquid N2. The powdered hearts were kept at -70°C. Cell-free extracts of frozen hearts were prepared by homogenizing 1 part by weight of powdered heart with 10 vol of homogenizing buffer (100 mM Tris-HCl, pH 7.4, which contained 2 mM dithiothreitol) using an Ultra-Turrax homogenizer (speed 20,000 r.p.m. for 30 s). Consistent results for phosphofructokinase activity were obtained when frozen heart powder was added to preweighed tubes containing homogenizing buffer that had been frozen in liquid N2 and the combined mixture homogenized during thawing at 5 °C. Thawing of the powdered heart before homogenization resulted in abnormally high phosphofructikinase activities, presumably due to the action of endogenous activators. The homogenate was centrifuged for 30 s at 8,000g and kept on ice. In these conditions the activity increased by ~10% per hour. 'Control' heart before homogenization resulted in abnormally high phosphofructokinase activities, presumably due to the action of endogenous siological fructose 6-phosphate concentration using a newly developed radioisotopic procedure². The assay has been previously shown to be specific for phosphofructokinase and to give values for maximal catalytic activity identical to those obtained using the conventional spectrophotometric assay of 16 nmol per min per mg protein (ref. 2). The assays were conducted in disposable plastic tubes (70×10 mm) at 30 °C and contained 10 µM glucose 6-phosphate, 3.3×10^4 d.p.m. [5-3H]glucose 6-phosphate (prepared from [5-3H]glucose2), ATP as indicated, 10 mM MgCl2 and 20 µ1 of cell-free supernatant (0.075-0.1 mg of protein) in a total volume of 0.2 ml of homogenizing buffer. Reactions were started by the addition of the extract and terminated by the addition of 0.5 ml of Dowex 1×8 (200-400 mesh) borate resin (1:1 in water), vortexed, then centrifuged for 3 min at 1,300g. A 0.25-ml portion of the supernatant (containing only ³H₂O) was mixed with 2 ml of a Triton X-based water-accepting scintillant and counted for radioactivity. The activity of phosphofructokinase is expressed in nmol of [5-³H]hexose 6-phosphate converted to ³H₂O per min per mg of protein, and was calculated from the d.p.m. in 3H2O and the specific radioactivity of hexose 6-phosphate. The specific radioactivity of hexose 6-phosphate was calculated from the d.p.m. added as [5-3H]glucose 6-phosphate and the sum of unlabelled glucose 6-phosphate and fructose 6-phosphate (added plus endogenous). Glucose 6-phosphate and fructose 6-phosphate were determined on neutralized perchlorate extracts of heart 12. The total concentration of hexose 6-phosphate in the assays was 10.7×10^{-6} and 14×10^{-6} M for control and adrenaline-treated extracts, respectively. Glycogen phosphorylase was measured using the filter disk assay of Gilboe et al. 13 as modified by Birnbaum and Fain 14 and was determined on extracts that had been passed through columns $(0.7 \times 2.5 \text{ cm})$ of Sephadex G-25. Protein was determined using the procedure of Lowry et al. 15 with bovine serum albumin as the standard. A total of four hearts (two control and two adrenalinetreated) were used. Mean values are shown.

tissue content of cyclic AMP. 10⁻⁵ M isoprenaline had no significant effect on the activity ratio of phosphofructokinase over the 15-min perfusion period. However, within 30 s there were marked increases in both cyclic AMP concentration and the activity ratio of phosphorylase. Both remained close to the maximal value throughout the 15-min non-recirculating perfusion. Phenylephrine (10⁻⁵ M), generally considered as predominantly an α -agonist but with some β activity in the rat⁵ increased the activity ratio of phosphofructokinase from 0.2 at 0 min to a maximal value of 0.65 at 1.5 min. The activation was similar to the time course previously reported for adrenaline1. Phenylephrine also produced an increase in the activity ratio of phosphorylase (100%). Naphazoline (10⁻⁵ M), an α -agonist⁷, increased the activity ratio of phosphofructokinase in a similar time-dependent manner to phenylephrine, reaching a maximum value of 0.55 at 1.5 min. Naphazoline had no effect on phosphorylase or cyclic AMP concentration.

The present findings suggest that short-term regulation of phosphofructokinase in rat heart by catecholamines is mediated by α -adrenergic receptors. This process may operate in anticipation of increased glucose released from the liver8 when catecholamines are released into the blood in emergency situations. The β -receptor component in the heart would lead to increased glycogenolysis, contractile rate and force. The α receptor component would separately permit increased flux through glycolysis from either myocardial glycogen stores or extra-myocardial glucose. Such a mechanism for α -receptormediated, cyclic AMP-independent control of phosphofructokinase would complement the observation by Keely et al.⁶ of an α -mediated glucose transport system in rat heart.

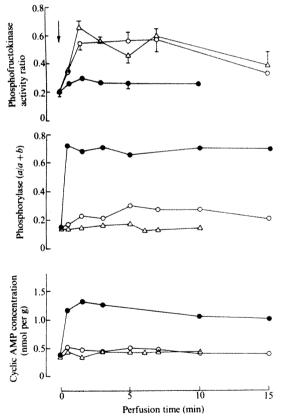

Fig. 2 Time course for the effects of α - and β -agonists on perfused rat heart. Hearts were perfused as described in Fig. 1. At the time indicated (arrow), medium containing 10^{-5} M isoprenaline (\blacksquare), 10^{-5} M naphazoline (△) or 10⁻⁵ M phenylephrine (○) was introduced. Non recirculating perfusion was continued until the hearts were freeze-clamped. The activity ratios of phosphofructokinase and glycogen phosphorylase were determined as described in Fig. 1 and the text. Solutions of agonists were freshly prepared in isotonic saline and mixed with warm (37 °C) oxygenated buffer immediately before introduction into the perfusion apparatus. Cyclic AMP was determined16 on neutralized perchlorate extracts of the frozen heart powders. Where indicated mean values ± s.e.m. have been calculated (bars) from at least three hearts. Other values are the mean of duplicate determinations from single hearts.

Activation of phosphofructokinase in rat heart by α -agonists seems to involve mechanisms quite different from those controlling glucose output in rat liver. Exton and co-workers8 have provided strong evidence that α -receptor stimulation in liver leads to Ca2+ release from intracellular stores. This in turn is believed to activate the Ca2+-dependent phosphorylase kinase that phosphorylates and activates phosphorylase. The present study indicates that activation of phosphorylase and phosphofructokinase are separate, suggesting a unique mechanism for phosphofructokinase activation. Furthermore, any increase in intracellular Ca2+ concentration should enhance contractility. In the present study, the α -agonist naphazoline, which activated phosphofructokinase, had no visable effect on either heart rate or force.

The mechanism by which α -agonsits activate heart muscle phosphofructokinase is unknown. It seems unlikely that changes in activity can be related to changes in the concentration of intracellular effectors1 even though a new activator of the liver enzyme has recently been described^{9,10}. Covalent modification including phosphorylation3 requires serious consideration as the change in activity is stable to gel filtration or dialysis (unpublished observations), providing buffers contain EDTA and sulphydryl reagents.

Evidence that LY-141865 specifically stimulates the D-2 dopamine receptor

K. Tsuruta, E. A. Frey, C. W. Grewe, T. E. Cote, R. L. Eskay* & J. W. Kebabian†

Experimental Therapeutics Branch, NINCDS, and *Laboratory of Clinical Science, NIMH, National Institutes of Health, Bethesda, Maryland 20205, USA

Available evidence suggests the existence of multiple categories of dopamine receptor¹⁻⁴. According to the classification scheme used here⁵, dopamine receptors can be divided into two general categories, D-1 and D-2. The dopamine receptors in the bovine parathyroid gland⁶⁻⁸ and carp retina^{9,10} exemplify the former category, and the dopamine receptors on the mammotrophs^{11,12} and melanotrophs^{13,14} of the pituitary gland exemplify the latter. Stimulation of a D-1 receptor enhances the formation of cyclic AMP, whereas stimulation of a D-2 receptor does not 4.5. The availability of dopaminergic agonists which specifically activate either a D-1 or a D-2 receptor would facilitate pharmacological investigation of the physiological responses to dopamine; however, to date, an agonist specific for the D-2 receptor has not

[†] To whom correspondence should be addressed.

been available. Dopamine and other catecholamines stimulate both types of receptor⁶⁻¹⁴; ergolines (such as lergotrile and lisuride) stimulate the D-2 receptor¹³⁻¹⁵ but antagonize the D-1 receptor^{8,16-18}; some agonists acting on the D-2 receptor (such as apomorphine) both stimulate and block the D-1 receptor^{6,8}. Although one report claims that S-584 may selectively stimulate the dopamine receptor on mammotrophs¹⁹, according to another, S-584 stimulates the striatal dopamine-sensitive adenylate cyclase²⁰. Several recently synthesized compounds containing various portions of the ergoline ring system stimulate the D-2 receptor on mammotrophs²¹. We report here that one of these ergoline analogues, LY-141865 or '38, R = pro'²¹, stimulates the D-2 receptor in the intermediate lobe (IL) of the rat pituitary gland but does not interact with the D-1 receptor in carp retina.

The melanotrophs of the IL synthesize and secrete α -melanocyte-stimulating hormone (α -MSH). Stimulation of the dopamine receptor in the rat IL inhibits basal release of α -MSH^{13,14}. LY-141865 mimics the ability of dopamine and dopaminergic agonists to diminish the basal release of α -MSH from the IL. Thus, during a 3-h incubation of dispersed cells derived from the neurointermediate lobe, LY-141865 decreased, in a dose-dependent manner, the basal release of α -MSH (Fig. 1 α). Half-maximal inhibition was achieved with \sim 30 nM LY-141865, maximal inhibition with a concentration \geqslant 1 μ M.

The melanotrophs of the rat IL also possess a β -adrenoreceptor, stimulation of which enhances adenylate cyclase activity¹⁵. Stimulation of the dopamine receptor diminishes basal adenylate cyclase activity and inhibits in a non-competitive manner the (-)isoprenaline-stimulated adenylate cyclase activity^{13-15,22}. Like other dopaminergic agonists, LY-141865 diminished the basal adenylate cyclase activity (Fig. 2, inset A) and the (-) isoprenaline-stimulated enzyme activity (Fig. 2 left, and inset B). Half-maximal inhibition of either basal or (-)isoprenaline-stimulated adenylate cyclase activity was achieved with ~30 μM LY-141865; maximal inhibition was achieved at concentrations $\geq 100 \,\mu\text{M}$ (Fig. 2 left, and inset B). Like other dopaminergic agonists, LY-141865 decreased the maximal response to (-)isoprenaline but did not affect the molar potency of (-)isoprenaline. Fluphenazine or (-)sulpiride (dopaminergic antagonists) prevented the inhibitory effects of LY-141865 (Fig. 2 left and insets A and B). Stimulation of the β -adrenoreceptor enhances the release of α -MSH; like other dopaminergic agonists, LY-141865 diminished the ability of B-adrenergic agonists to enhance α -MSH release (Fig. 1b).

To examine the actions of LY-141865 on rat IL adenylate cyclase in the absence of β -adrenergic agonists, the drug was tested on rat IL tissue previously treated with cholera toxin. Adenylate cyclase activity was substantially greater in homogenates of cholera toxin-treated tissue than in homogenates of either fresh or control tissue (Table 1). The dopamine receptor remained functional after treatment of IL tissue with cholera toxin. Both dopamine and apomorphine (a dopaminergic agonist) markedly diminished enzyme activity in homogenates of cholera toxin-treated tissue (Table 2); (-)sulpiride or fluphenazine (dopaminergic antagonists) prevented the inhibitory effect of both dopaminergic agonists. Like dopamine and apomorphine, LY-141865 decreased adenylate cyclase activity in homogenates of cholera toxin-treated tissue (Fig. 2, right); half-maximal inhibition was achieved with 30 µM LY-141865 (Fig. 2, insert C). The inhibitory effect of LY-141865 was attenuated in a dose-dependent manner by spiroperidol or (-)sulpiride; (-)sulpiride was 100-fold more potent than the (+)sulpiride (Fig. 2, right).

To determine whether LY-141865 is a specific D-2 agonist, the compound was tested on the dopamine-sensitive adenylate cyclase of carp retina, a tissue displaying an unusually large (four- to fivefold) dopamine-induced stimulation of adenylate cyclase activity^{9,10}. In this test system, LY-141865 displayed no activity, either as a dopaminergic agonist or as a dopaminergic antagonist (Table 3); lergotrile failed to stimulate adenylate

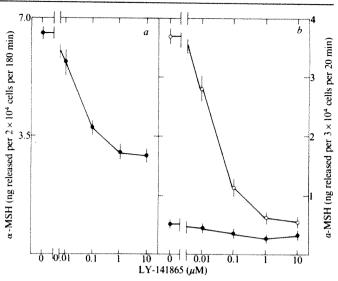

Fig. 1 LY-141865 inhibits release of α -MSH from dispersed neurointermediate lobe cells. a, Incubations were performed for 180 min in the presence of the indicated concentrations of LY-141865 (trans-(\pm)-4,4a,5,67,8,8a,9-octahydro-5-propyl-2H-pyrazolo-(3,4-g)quinoline). b, Incubations were performed for 20 min in the absence (\bigoplus) and the presence (\bigcirc) of $0.1~\mu$ M(-)isoprenaline and the indicated concentrations of LY-141865. Previously described procedures 13 were used for the preparation of dispersed neurointermediate lobe cells, the experimental incubations and the assay of α -MSH.

cyclase activity but diminished the stimulatory effect of dopamine.

These results indicate that LY-141865 discriminates between the D-1 and D-2 receptors. Clearly LY-141865 does not interact with the D-1 receptor: it did not stimulate the D-1 receptor in the carp retina, and unlike lergotrile, LY-141865 did not block this receptor²³. It is also clear that LY-141865 stimulates

Table 1 Cholera toxin increases adenylate cyclase activity in rat IL

Tissue	Adenylate cyclase activity (pmol cyclic AMP per mg protein per min)			
Fresh	43 ± 2			
2 h control	47 ± 21			
2 h + 30 nM cholera toxin	361 ± 29			

IL tissue was dissected and adenylate cyclase activity assayed as described in Fig. 2 legend. Tissue was homogenized and adenylate cyclase activity assayed either immediately after dissection (fresh) or after incubation for 2 h at 37 °C in 5 ml of RPMI 1640 medium (equilibrated with a mixture of 95% O_2 and 5% CO_2) containing 25 mM HEPES, $100~U~ml^{-1}$ penicillin, $100~\mu g~ml^{-1}$ streptomycin, and cholera toxin as indicated. Data represent mean $\pm s.e.m.$ for five replicate homogenates.

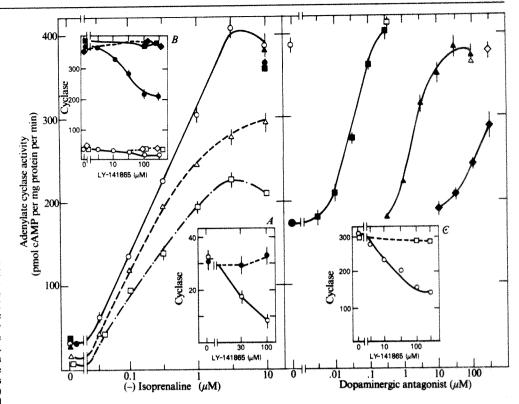

Table 2 Dopaminergic inhibition of adenylate cyclase activity in cholera toxin-treated rat IL

Adenylate cyclase activity

	(pmol cyclic AMP per mg protein					
	Antagonist					
Agonist	None	Fluphenazine (10 µM)	(-)Sulpiride (100 μM)			
None Dopamine (100 μM) Apomorphine (10 μM)	433±14 106±3 150±3	465±10 453±7 490±7	420 ± 4 475 ± 9 500 ± 11			

IL tissue was dissected and incubated for 2 h in the presence of 30 nM cholera toxin as described in Table 1 legend. At the end of the incubation, the tissue was homogenized and adenylate cyclase activity assayed in the presence of the indicated concentrations of test substances, as described in Fig. 2 legend. Data represent mean ±s.e.m. for four replicate samples in a single experiment.

Fig. 2 Left: LY-141865 decreases basal and (-)isoprenaline-stimulated adenylate cyclase activity in rat IL. Adenylate cyclase activity was assayed in the presence of the indicated concentrations of (-)isoprenaline alone (O) or in combination with 30 µM LY-141865 (Δ), 100 μM LY-141865 (□), 10 μM fluphenazine (●), 10 µM fluphenazine and 30 µM LY-141865 (▲) or 10 µM 100 µM fluphenazine and 141865 (). Inset A: Data for basal adenylate cyclase activity are replotted with a larger scale for the ordinate. Adenylate cyclase activity was assayed in the presence of the indicated concentrations of LY-141865 alone (O) or in combination with 10 uM fluphenazine (). Inset B: In a separate experiment, adenylate cyclase activity was assayed in the presence of the indicated concentrations of LY-141865 alone (O) or in combination with 10 µM fluphenazine (\Box), 100 μ M (-)sulpiride (\diamondsuit), 3 μ M (-)isoprenaline (\spadesuit), 3 μ M (-)isoprenaline and 10 μ M fluphenazine (\blacksquare) or 3 µM (-)isoprenaline and 100 µM (-)sulpiride (◆). Right: Dopaminergic antagonists reverse the inhibition by LY-141865 of adenylate cyclase activity in cholera toxin-treated IL tissue. IL tissue was treated with cholera toxin (30 nM, 2 h) as described in Table 1 and adenylate cyclase activity was determined in the absence of drugs (O) or in the presence of the indicated

concentrations of spiroperidol (□), (-)sulpiride (△), (+)sulpiride (⋄), 100 µM LY-141865 (♠) or 100 µM LY-141865 in combination with the indicated concentrations of spiroperidol (□), (-)sulpiride (♠) and (+)sulpiride (♠). Inset C: In a separate experiment, IL tissue was treated with cholera toxin (30 nM, 2 h) and adenylate cyclase activity determined in the presence of the indicated concentrations of LY-141865 alone (O) or in combination with 100 μ M (-)sulpiride (\square). Adenylate cyclase activity was determined using a previously described assay system¹⁵ containing: 80 mM, Tris-HCl (pH 7.4), 1 mM MgSO₄; 0.8 mM EGTA; 10 mM theophylline; 0.25 mM ATP; 0.01 mM GTP; intermediate lobe tissue, 2.5-3.5 μ g of protein; and drugs as indicated in Tables 1 and 2 and Figs 1 and 2. The assay system was incubated for 10 min at 30 °C, and the reaction stopped by boiling for 2 min. Cyclic AMP concentration was determined by the method of Brown et al.27, protein content by the method of Lowry et al.28.

the D-2 dopamine receptor in the rat IL because (1) LY-141865 mimics the ability of dopamine and dopaminergic agonists to decrease basal or (-)isoprenaline-stimulated release of α -MSH; (2) LY-141865 mimics the inhibitory actions of dopamine and dopaminergic agonists on adenylate cyclase activity in homogenates of fresh or cholera toxin-treated tissue; and (3) the inhibitory effects of LY-141865 on adenylate cyclase activity are reversed by dopamine antagonists, including the selective D-2 antagonist, (-)sulpiride²⁴. LY-141865 is substantially more potent on intact cells of the rat IL than in the cell-free adenylate cyclase assay system (compare potency in Figs 1 and 2); the reasons for this discrepancy are unknown. The previous

demonstration²¹ that LY-141865 lowers the level of serum prolactin in reserpine-treated male rats is in accord with the conclusion that LY-141865 is an agonist on the D-2 receptor. The availability of drugs selectively stimulating either the D-1

receptor (such as SKF 38393A)25 or the D-2 receptor (such as

LY-141865) may facilitate pharmacological analysis of the

physiological responses to dopamine. Furthermore, because

Table 3 LY-141865 fails to stimulate adenylate cyclase of fish retina

Adenylate cyclase activity (pmol cyclic AMP per mg protein per min)

m .		rest compound	
Dopamine concentration (µM)	None	LY-141865 (100 μM)	Lergotrile (100 μM)
0 10	$11.1 \pm 0.7 \\ 35.5 \pm 1.7$	9.4 ± 0.8 36.3 ± 2.4	6.2 ± 1.1 12.5 ± 0.7

Retinal tissue was obtained from goldfish purchased at a local pet store. Adenylate cyclase activity was assayed as described in Fig. 2 legend. Data represent mean ±s.e.m. for four replicate samples obtained in a single experiment.

LY-141865 penetrates the blood-brain barrier after its systemic administration²¹, it may be of use in the treatment of parkinsonism (as are the dopaminergic ergots²⁶).

Note added in proof: Euvard et al. (Neuropharmacology 19, 376-386; 1980) describe two other compounds which seem to act as selective agonists on the D-2 receptor.

Trypanocidal activity of daunorubicin and related compounds

J. Williamson & T. J. Scott-Finnigan

Division of Parasitology, National Institute for Medical Research, Mill Hill, London NW7 1AA. UK

M. A. Hardman & J. R. Brown*

Department of Pharmaceutical Chemistry, School of Pharmacy, Leicester Polytechnic, PO Box 143, Leicester LE1 9BH, UK

The anthracycline antibiotic daunorubicin is, in vitro, one of the most potent trypanocidal agents reported1; it permanently abolishes the infectivity of African trypanosomes at less than nanomolar concentrations. In contrast, other anthracyclines such as doxorubicin and nogalamycin must be present in millimolar concentrations to achieve the same effect (Table 1). Despite its uniquely high activity in vitro, daunorubicin is totally inactive against trypanosomes in infected rodents1. An investigation of this lack of in vivo activity suggested that uptake into trypanosomes is only transient². We therefore tried to prolong exposure of trypanosomes to the drug by coupling it to a carrier macromolecule. The use of such a carrier should delay removal of the drug from the blood and simultaneously exploit the endocytotic properties of trypanosomes. Ferritin and albumin were chosen as potential carriers as these proteins are endocytosed by trypanosomes3,4. We report here that when the drug was attached by a stable linkage, activity was not maintained, but when attached by a labile covalent linkage the preparation was active both in vitro and in vivo, indicating the desirability of testing other macromolecules, such as dextran⁵, as carriers for trypanocidal drugs.

As none of the daunorubicin analogues tested (see Table 1. and Fig. 1) reproduce the high in vitro trypanocidal activity of daunorubicin, the loss of activity of this drug in vivo must be overcome. We first tested a DNA-daunorubicin complex⁶ but it was inactive. As this product acts as a slow-release form of drug? rather than a true carrier, covalent attachment of drug to possible carriers was then investigated. Bovine serum albumin (BSA) and ferritin were chosen as carriers because of the likelihood of their endocytosis by trypanosomes^{3,4}. The first albumin conjugate was prepared by oxidative cleavage of the amino sugar of the drug to yield an aldehyde which was reacted with the protein to give a Schiff's base—this was then reduced with borohydride⁸. The product was almost inactive (Table 1), possibly due to destruction of the amino sugar unit or to the stability of the linkage. Therefore a second conjugate⁸ was prepared using glutaraldehyde to form Schiff's bases simultaneously with the amino group of daunorubicin and a free amino group of the protein. This product retained activity in vitro (Table 1) and was significantly active in vivo (Table 2). As Schiff's bases are susceptible to hydrolysis, the rate of drug release from the conjugate in aqueous solution (pH 7.4) at 37 °C was monitored (by size-exclusion HPLC); release seemed to be a first-order process with a half life of ~100 h.

The retention of activity only when the carrier-binding linkage is labile suggests that the drug must be released before it can exert its effects. Because of the success of albumin as a carrier, we also prepared ferritin conjugates in which daunorubicin was linked by the glutaraldehyde method⁸. These were also found to have high activity in vitro and in vivo (Tables 1 and 2). These glutaraldehyde-coupled daunorubicin-albumin and daunorubicin-ferritin complexes were the first daunorubicin preparations to clear trypanosomes from the blood of infected mice for an extended period. For 20-30 h after treatment, the proportion of abnormal trypanosomes rose to almost 100%, the highest proportions coinciding with a sharp fall in parasitaemia.

Daunorubicin-ferritin (C)	15	0/13

Mice with a patent parasitaemia were given a single intraperitoneal dose of the compound being tested 24-48 h after infection. Control mice were uniformly dead 4-5 days after infection. Generally, the amounts of the conjugates available were small and consequently the numbers of mice used in the tests were limited. G denotes conjugation by the glutaraldehyde method⁸; C denotes non-covalent binding of drug in the ferritin iron core.

Fig. 1 Structures of the compounds tested for trypanocidal activity.

Fluorescence microscopy showed that the parasites took up the complexed drug progressively for up to 12 h after treatment and retained it thereafter, unlike the transient uptake peaking at 1.5-2 h of the free drug. This altered pattern of uptake suggests that drug is taken up as the drug-protein complex; the pre-

paration thus seems to act as a true endocytotic carrier.

Ferritin contains an iron (Fe³⁺) core surrounded by 24 subunits of apoferritin and can be reconstituted from apoferritin in the presence of Fe3+ or Fe2+ and oxidizing agents9. As daunorubicin forms a chelate with iron, preparation of a daunorubicin-ferritin complex by sequestration of the drug in the iron core of ferritin was attempted by reconstitution of ferritin from apoferritin and Fe²⁺ with a weak oxidizing agent, in the presence of daunorubicin. A high uptake of drug was achieved and despite the non-covalent nature of the complex, the drug was not released on gel chromatography of the complex in 1M NaCl or in 2% SDS in 8M urea; the product was however less active than the covalently bound preparation and showed no in vivo activity (Tables 1 and 2).

The need for new drugs active against African trypanosomiases, both human and animal, is widely recognized 10. Our results clearly demonstrate that daunorubicin has considerable potential as a trypanocide as: (1) it shows unparalleled trypanocidal activity in vitro; (2) it can be conjugated to macromolecular carriers to give soluble complexes which retain activity in vivo; (3) it is structurally distinct from existing trypanocides and so should lack cross-resistance with these drugs; and (4) it has considerable capacity for structural variation.

We thank Dr Diane J. McLaren for providing electron micrographs, Miss Jane C. Marsh for technical assistance and the Wellcome Trust for support (to M.A.H.). We also thank the suppliers of the daunorubicin analogues listed in Table 1.

Interactions of daunomycin and melanotropin-daunomycin with DNA

Gary Wiesehahn*, Janos M. Varga† & John E. Hearst*

The specific recognition of fluorescein-melanotropin and melanotropin-ferritin-fluorescein conjugates by melanotropin (MSH) receptors on the surface of murine melanoma cells suggested the possibility of specific site-directed chemotherapy of melanomas¹⁻³. An MSH-daunomycin conjugate has been shown to be more toxic to mouse melanoma cells than free daunomycin, and, at the same concentration, it was not toxic to mouse 3T3 fibroblast cells. Unconjugated daunomycin was equally toxic to both cell lines4. We report here investigation of the interactions of purified DNA with free daunomycin and with MSH-daunomycin conjugate using spectrophotometry and also an agarose gel assay that detects the unwinding of DNA due to ligand binding. We found an association constant of $4.8\times$ 106 M⁻¹ and an unwinding angle of 10±1.5° for daunomycin, but no detectable binding and an association constant of $<4.8 \times$ 103 M-1 for MSH-daunomycin conjugate. We conclude that the cytotoxicity of MSH-daunomycin is not due to its binding to DNA.

The cytotoxicity of daunomycin is thought to be due to its strong interaction with cellular DNA^{5.6}, thereby interfering with both RNA and DNA synthesis^{7.8}. The experiments described here were designed to determine whether the interaction of daunomycin with DNA is affected by the covalent coupling of daunomycin to MSH. The change in the absorption spectrum of daunomycin as increasing amounts of supercoiled Col El DNA are added is shown in Fig. 1A. With increasing concentration of DNA, the absorption maximum shifts gradually from 480 nm to 505 nm and the absorption of daunomycin decreases towards a limit that represents the spectrum of daunomycin in the fully complexed form. There appears to be an isosbestic point at ~545 nm. Assuming independent binding sites, Scatchard analysis⁹ will result in the following expression:

$$\frac{r}{P} = K_{APP} \times (B_{APP} - r)$$

Following the nomenclature of Bresloff and Crothèrs¹⁰, r is the ratio of the concentration of bound ligand to the total concentration of DNA base pairs, K_{APP} is the apparent association constant for the interaction of DNA and ligand, B_{APP} is the

number of apparent binding sites for ligand per base pair and P the concentration of free ligand.

A Scatchard plot calculated from the spectrophotometric results on daunomycin binding is shown in Fig. 1B. The plot reveals a $K_{\rm APP}$ of $4.8\times10^6\,{\rm M}^{-1}$ and a $B_{\rm APP}$ of 0.24 for the binding of daunomycin to DNA. These values are in reasonable agreement with published values of $6.6\times10^6\,{\rm M}^{-1}$ and 0.36 for daunomycin binding to calf thymus DNA in 0.1 M Tris-HCl (pH 7.0)⁶.

In contrast, Fig. 1C shows that minimal spectral change (only a very slight initial depression in the absorption profile) occurred when Col El DNA was added to the MSH-daunomycin conjugate. Thus no binding was detected by this method.

An additional test for DNA binding is the unwinding assay in which supercoiled DNA is relaxed with nicking-closing enzyme in the presence of compounds that bind DNA. The result is a complex between drug and covalently closed DNA with the DNA in a relaxed conformation. On removal of the drug the DNA becomes superhelical, and the number of superhelical turns can be determined by agarose gel electrophoresis¹¹.

Figure 2A illustrates a comparison of DNA-unwinding assays with daunomycin (lanes a-f) and MSH-daunomycin conjugate (lanes g-l) at comparable drug/DNA ratios. Daunomycin clearly has a large effect on the superhelical density of DNA,

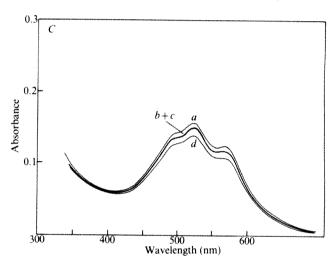

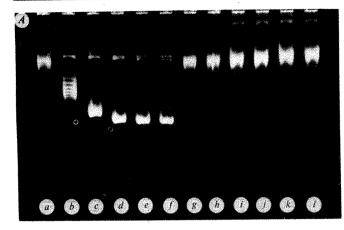

Fig. 1 A, effect of supercoiled colicin El (Col El) plasmid DNA. isolated from E. coli JC 411 thy (Col El), on the absorption spectrum of daunomycin. The incubation mixture contained 2.89 × 10⁻⁵ M daunomycin in 0.04 M Tris-HCl, pH 8.0, 5 mM NaOAc, 0.5 mM EDTA, 0.2 M NaCl. Absorbance was measured using a 1-cm path length quartz cuvette in a Cary 118 spectrophotometer. at the following DNA concentrations (M): curve a, zero; b, 2.57×10^{-5} ; c, 1.03×10^{-4} ; d, 2.14×10^{-4} . These concentrations are in moles of DNA base pairs per litre. B, Scatchard plot of the data in A, plotted according to the method of Muller and Crothers¹ determined the ratio of free to bound daunomycin at intermediate points by assuming the absorption spectrum is a linear combination of the free and fully complexed daunomycin spectra. The absorbance at 470 nm was used for this calculation as at this wavelength the difference between free and bound daunomycin is greatest. For example, we assumed that the ratio of free to bound daunomycin is 2:1 when the absorption at 470 nm is one-third of the way from the absorption of free daunomycin to the absorption of fully complexed daunomycin. Knowing the total concentration of daunomycin, it is then simple to calculate the concentrations of free and bound daunomycin. The absorption data were corrected for the dilution due to addition of DNA solution. C, effect of supercoiled Col El DNA on the absorption spectrum of MSHdaunomycin conjugate. The incubation mixture contained 2.11 × M conjugate in the buffer described in A. The absorbance was measured at the following DNA concentrations (M): curve a, 0; b, 1.03×10^{-5} ; c, 2.57×10^{-5} ; d, 3.48×10^{-4} . The slight depression in the absorbance spectrum is due to dilution of the conjugate on addition of the DNA. The conjugate was prepared as described by Varga et al.4.

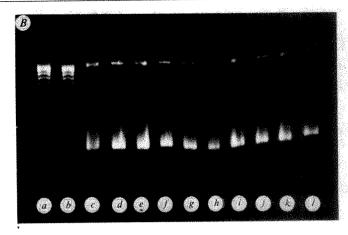

Fig. 2 A, agarose slab gel of Col El DNA $(4.3 \times 10^{-5} \text{ M})$ relaxed with nicking-closing enzyme in the presence of increasing amounts of daunomycin (lanes a-f) or MSH-daunomycin conjugate (lanes g-l). Lanes: a, no daunomycin present; b, 2.05×10^{-6} M; c, 4.10×10^{-6} M; d, 6.14×10^{-6} M; e, 8.19×10^{-6} M; f, 1.02×10^{-5} M; g, no conjugate present; h, 1.49×10^{-6} M; f, 1.02×10^{-6} M; f, 1.02reacted with nicking-closing enzyme in the presence of increasing amounts of daunomycin-MSH conjugate. Lanes, a, no conjugate present; b, 7.50×10^{-6} M; c, 2.25×10^{-5} M; d, 3.75×10^{-5} M; e, 5.25×10^{-5} M; f, 6.75×10^{-5} M; g, 8.25×10^{-5} M; h, 9.75×10^{-6} M; i, 1.12×10^{-4} M; j, 1.28×10^{-4} M; k, 1.42×10^{-4} M; l, 1.58×10^{-4} M. If we assume that the binding of one molecule of conjugate would unwind DNA by 10° as does the binding of unconjugated daunomycin, then the binding of 1% of the conjugate molecules (at a base pair/conjugate ratio of 1:1) would cause about a two-band shift in the DNA distribution on the agarose gel $(64 \times 10^{\circ} = 640^{\circ})$ or 1.8 superhelical turns). This two-band shift should be easily detected on the gel. As no shift was observed, we conclude that the ratio of bound to unbound conjugate is <0.01. This ratio can be compared with the ratio of 12 bound daunomycin molecules per unbound daunomycin molecule calculated from the Scatchard equation at low values of r. Thus, the bound/unbound ratio for the conjugate is at least three orders of magnitude less than for daunomycin, and $K_{APP} < 4.8 \times 10^3 \,\mathrm{M}^{-1}$ for the conjugate.

whereas the conjugate has no detectable effect. Using the binding constant $4.8 \times 10^6 \,\mathrm{M}^{-1}$ and assays such as are shown in Fig. 2A, we have determined an unwinding angle of $10 \pm 1.5^{\circ}$ for each bound daunomycin molecule following the method previously described¹². This again agrees with the value of $12 \pm 3.3^{\circ}$ (corrected to an ethidium unwinding angle of 28°) published previously by Waring¹²

As shown in Fig. 2B, increasing the concentration of MSHdaunomycin conjugate in an attempt to detect low-level binding to DNA does not result in the production of a population of DNA molecules of intermediate superhelical density as in lanes b and c of Fig. 2A. It results instead in inhibition of nickingclosing activity (lanes c-l, Fig. 2B). The highest concentration of MSH-daunomycin conjugate that produced fully relaxed Col El DNA corresponded to one conjugate molecule per base pair (~6.400 conjugate molecules per Col El DNA molecule). The inhibition of nicking-closing enzyme by MSH-daunomycin conjugate seems to be due to an interaction between the nicking-closing enzyme and the conjugate because increased concentrations of enzyme require increased concentrations of conjugate for inhibition. This inhibition seems to be mainly due to MSH and occurs at rather high concentrations of conjugate (50 μM) (data to be published elsewhere).

We could not detect any binding of MSH-daunomycin conjugate to DNA which results in a shift of the absorption spectrum of daunomycin nor any which distorts the DNA helix enough to be detected in a DNA-unwinding assay. We conclude from the DNA-unwinding assay that the association constant for binding of the conjugate to DNA is $<4.8\times10^3$ M⁻¹. This lack of binding is consistent with the observation of Zunino et al.6, who showed that the N-acetylation of the sugar ring of daunomycin reduces the affinity for DNA by more than two orders of magnitude. The addition of the large MSH molecule to the split sugar ring (which also results in the removal of the primary amino group) might be expected to decrease the affinity of daunomycin to DNA even more.

The killing of mouse melanoma cells by melanotropindaunomycin conjugate must therefore be explained by a mechanism other than direct binding of the conjugate to DNA. It has recently been shown that adriamycin, a structural analogue of daunomycin, perturbs the cell membrane by lowering the temperature of gel-to-liquid transition¹³. Thus the site of

action of melanotropin-daunomycin might be the cell membrane. However, the effects of transglutaminase inhibitors on the toxicity of the conjugate strongly suggest an effect on internalization. It has been demonstrated that inhibitors of transglutaminase inhibit receptor-mediated endocytosis of polypeptide hormones¹⁴. If endocytosis of melanotropindaunomycin is essential for toxicity, we could expect that inhibitors of transglutaminase would prevent the toxic effects of the conjugate. We have, indeed, found that ammonium acetate (1 mM), methylamine (0.1 mM) and chloroquine (10⁻⁷ M) all reduce the toxic effects of MSH-daunomycin by about 50 % 15 As direct binding of the conjugate to DNA does not explain its toxic effect, we must therefore consider two alternative explanations—that the free and conjugated toxins kill the cells by different mechanisms, or that the internalized MSHdaunomycin is metabolized to a form that can bind to DNA and thereby interfere with transcription and replication. We think the second mechanism more likely.

Enteropancreatic circulation of digestive enzymes does not exist in the rat

Gerhard Rohr*, Horst Kern† & George Scheele‡

* Medizinische Universitätsklinik and † Institut für Anatomie und Zellbiologie, Universität, D-3550 Marburg/Lahn, FRG ‡ Department of Cell Biology, Rockefeller University, New York, New York 10021, USA

The hypothesis of an enteropancreatic circulation 1-3, that digestive enzymes are absorbed intact across the intestinal epithelium, are circulated through the bloodstream and resecreted by the exocrine pancreas, has generated considerable discussion4-6 and has been accepted by a number of medical scientists⁷⁻⁹. However, the data presented in support of this hypothesis do not demonstrate with certainty that labelled proteins introduced into the bathing medium^{1,3}, intestinal tract^{1,2} or bloodstream² appear unmodified in pancreatic juice. We have now critically examined that part of the hypothesis which proposes that pancreatic secretory proteins are taken up from the bloodstream and secreted intact into the pancreatic juice. Injection of ³⁵S-methionine-labelled rat pancreatic amylase into the blood circulation of unanaesthetized rats resulted in the appearance of radioactivity in all exocrine pancreatic proteins and showed a distribution which was indistinguishable from that following the intravenous administration S-methionine. These findings are not consistent with the direct transport of amylase from the blood circulation to the pancreatic ductal lumen, but are consistent with metabolic degradation of the polypeptide probe and reutilization of the free 35S-methionine for the synthesis and secretion of the entire complement of pancreatic exocrine proteins. In contrast, analysis of bile by similar methods indicated the presence of a haematobiliary pathway, which accounted for the excretion of 0.8% of exocrine pancreatic proteins injected into the blood circulation.

35S-methionine-labelled rat pancreatic amylase was injected into the blood circulation of nonanaesthetized rats and the appearance of radioactivity in pure pancreatic juice was followed with time and further analysed by two-dimensional isoelectric focusing/SDS-gel electrophoresis followed by fluorography. Rats (250-300 g) were prepared for study as follows. The pancreatic duct was cannulated with a 0.6-mm PVC catheter, fixed with a surgical ligature and routed subcutaneously to the nape of the neck. Bile flow into the intestinal tract was re-established during the surgical procedure using a short cannula of the same size. After the operation rats were maintained in restraining cages, which allowed exercise and free access to food and water. Rats were studied 6-18 h after the operation when pancreatic secretion rates were stable, usually between 450 and 500 µl h⁻¹. As the control, ³⁵S-methionine was injected into the tail vein of nonanaesthetized rats.

Trichloroacetic acid (TCA)-insoluble radioactivity first appeared in pancreatic juice 1.5 h after the injection of ³⁵S-labelled amylase (Fig. 1). Radioactivity increased slowly thereafter and peaked at 6 h. In contrast, after the injection of ³⁵S-methionine, TCA-insoluble radioactivity appeared in pancreatic juice within 30 min and peaked at 2 h. In both conditions, we observed no difference between TCA-insoluble and total radioactivity, indicating that free methionine was not released into the ductal fluid. These findings clearly differ from those of previous investigators who claimed that pancreatic proteins were transported from the interstitial space of the exocrine pancreas to the duct lumen within 15 min.

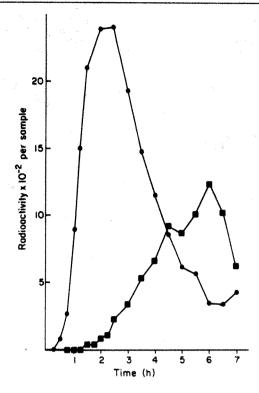

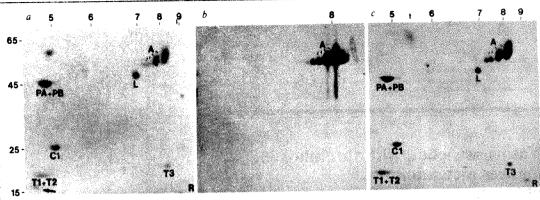

Fig. 1 Appearance of radioactivity in pancreatic juice as a function of time after intravenous administration of ³⁵S-methionine-labelled rat pancreatic amylase (2×10⁶ c.p.m.) compared with ³⁵S-methionine (1.5×10⁷ c.p.m.). TCA-insoluble radioactivity is shown on the ordinate for 100-μl samples collected after the injection of amylase (■) or for 10-μl samples after the injection of ³⁵S-methionine (●). Radiolabelled amylase was prepared as follows. Exocrine pancreatic proteins contained in rat pancreatic lobules were labelled with ³⁵S-methionine for 3 h as previously described for the dog pancreas ¹². A crude zymogen granule fraction was isolated by differential sedimentation and proteins contained within it were liberated by treatment with 0.2 M NaHCO₃, pH 8.5. ³⁵S-methionine-labelled amylase was precipitated with shellfish glycogen by the procedure of Schramm and Loyter ¹³. The glycogen amylase precipitate was washed twice as described previously ¹¹ and solubilized in normal saline.

Radioactive protein(s) injected into the blood circulation and those appearing in pure pancreatic juice were separated by two-dimensional isoelectric focusing/SDS-gel electrophoresis using the procedure of Bieger and Scheele 10 and analysed by Coomassie blue staining and fluorography. Figure 2a shows the Coomassie blue-staining pattern of proteins found in rat pancreatic juice. Most of these proteins have been identified according to actual or potential enzyme activity (J. Schick, H. Kern and G. Scheele, unpublished observations) by methods previously described for the guinea pig pancreas¹¹. Figure 2b shows the distribution of radioactive proteins injected into the blood circulation and confirms that the injected material contained exclusively ³⁵S-methionine-labelled rat pancreatic amylase. Figure 2c shows that radioactivity is distributed among all exocrine proteins in pancreatic juice at the 6-h time point (maximal radioactivity). After injection of 35S-methionine, pancreatic juice showed a similar distribution of radioactive proteins as judged by both fluorography and liquid scintillation spectroscopy following excision of Coomassie blue-stained spots and solubilization of the acrylamide pieces (data not shown). Samples of pancreatic juice collected earlier, 3-6 h after the injection of radiolabelled amylase, also showed a similar distribution of radioactivity among all secreted proteins.

The per cent radioactivity precipitated with shellfish glycogen allowed us to quantify the distribution of amylase among

Fig. 2 Analysis of proteins injected into the blood circulation or collected in 65 pancreatic juice by twodimensional isoelectric focusing/SDS-gel electrophoresis. a Shows the blue-staining Coomassie of proteins pattern contained in rat pancreatic juice; b shows a fluorograph of 35S-methionine-labelled 25 rat pancreatic proteins precipitated with shellfish glycogen and subsequently injected into the blood

circulation; and c shows a fluorograph of proteins contained in pancreatic juice 6 h after injection of the radiolabelled material presented in b. After intravenous administration of 35 S-methionine, the distribution of radioactive proteins secreted into the pancreatic juice showed a fluorographic pattern similar to that observed in c. Each of the gels in panels a-c were impregnated with diphenylexazole as required for fluorography. Proteins are labelled according to their actual or potential enzyme activities: A, amylase; L, lipase; PA, procarboxypeptidase A; PB, procarboxypeptidase B; C, chymotrypsinogen; T, trypsinogen; and R, ribonuclease. The arrow in a identifies soybean trypsin inhibitor added to the samples of pancreatic juice to prevent autoactivation of pancreatic proteins during their analysis by the two-dimensional gel procedure. The upper abscissae give the isoelectric points of proteins; the left ordinate gives the apparent molecular weight ×10⁻²

radioactive proteins injected into the blood circulation and those secreted into pancreatic juice collected between 2 and 7 h during the experiment. Although the radioactivity injected was exclusively represented by amylase (99.0%), only 30.7% of the radioactivity which subsequently appeared in pancreatic juice was represented by this enzyme. This contribution by amylase was identical to that observed in a crude zymogen granule fraction after labelling of rat pancreatic lobules with 3 methionine (29.9%). As the distribution of radioactivity after injection of 35S-labelled amylase was indistinguishable from that resulting from injection of 35S-methionine, we conclude that the amylase injected into the blood circulation was taken up by tissues in the rat and degraded to individual amino acids and that the resulting free ³⁵S-methionine, circulated through the

Fig. 3 Analysis of proteins contained in bile by two-dimensional isoelectric focusing/SDS-gel electrophoresis. Rat pancreatic proteins were labelled with ³⁵S-methionine as described in Fig. 1 legend. After injection of the entire complement of radioactive proteins into the blood circulation, bile samples were collected at 5-min intervals. a Shows the Coomassie blue-staining pattern and b the fluorographic pattern of proteins contained in the bile sample collected between 20 and 30 min. Radioactive pancreatic proteins observed in bile are labelled by abbreviations described in Fig. 2 legend. The radioactive protein with an isoelectric point of 4.8 and M_r (molecular weight) ~72,000 in b represents an acidic glycoprotein normally found in low levels in rat pancreatic secretion. The upper abscissae give the isoelectric points of proteins and the left ordinate gives the apparent molecular weight ×10-

bloodstream, was used for synthesis of the entire complement of secretory proteins by the exocrine pancreas. No degradation was observed when 35S-labelled amylase was incubated with rat serum at 37 °C for 7 h. Presumably the bulk of amylase was taken up by the reticuloendothelial system because rat pancreatic amylase contains no attached carbohydrate. These findings indicate that rat pancreatic amylase is not directly transported from the blood circulation to the pancreatic juice. We therefore conclude that this component of the proposed enteropancreatic circulation for digestive enzymes does not exist.

Other studies strongly support our conclusions. Injection of 35S-methionine-labelled guinea pig pancreatic proteins into the blood circulation of the rat resulted in the appearance of TCAinsoluble radioactivity in pancreatic juice after I h. Separation of proteins contained in pancreatic juice by the two-dimensional gel procedure, which discriminates guinea pig from rat exocrine pancreatic proteins, followed by fluorography, indicated that radioactivity was exclusively associated with rat proteins. The sensitivity of our analysis using the methods described would have allowed the detection of 0.002% of radioactive guinea pig pancreatic proteins.

In contrast with our studies analysing pancreatic juice, the analysis of bile after injection of pancreatic proteins into the blood circulation indicated that 35S-labelled rat pancreatic proteins appeared rapidly, within 5 min, in biliary fluid. Figure 3 compares the Coomassie blue and fluorographic pattern of proteins contained in a sample of bile collected 20-30 min after injection of radioactive proteins into the blood circulation. Pancreatic proteins, which appeared in bile, represented 0.8% of the injected radioactivity and the appearance of negatively charged proteins was favoured over positively charged proteins (compare Figs 3b and 2c). These observations indicate not only the presence of a haematobiliary pathway for exocrine pancreatic proteins, but provide a powerful positive control for our studies into the possible existence of a haematopancreatic pathway. Taken together, our data convincingly demonstrate, to the level of 0.002%, that this latter putative pathway, at least in the rat, does not exist.

Vasoconstriction with thromboxane A. induces ulceration of the gastric mucosa

B. J. R. Whittle, G. L. Kauffman & S. Moncada

Department of Prostaglandin Research, Wellcome Research Laboratories, Langley Court, Beckenham, Kent BR3 3BS, UK

Thromboxane A₂ (TXA₂) is formed from the fatty acid precursor, arachidonic acid (AA), by the sequential actions of the enzymes cyclooxygenase and thromboxane synthetase1. It is readily generated by platelets and is a potent vasoconstrictor and inducer of platelet aggregation 1,2. Studies in dogs show that the addition of AA to blood flowing through an incubation coil leads to production of TXA2, characterized by its instability and its ability to contract isolated strips of vascular tissue3. We now report that the formation of TXA2 from AA in blood can be inhibited by 1-benzylimidazole, a thromboxane synthetase inhibitor, and selectively by very low doses of indomethacin. In conditions of TXA2 inhibition, a vasodilator AA metabolite, presumably prostacyclin, is formed in the stomach. We show that TXA2 is a powerful gastric vasoconstrictor and can extensively damage the gastric mucosa, and suggest that it may be involved in the pathogenesis of certain ulcerative disorders of

Segments of acid-secreting fundic mucosa from the stomachs of pentobarbitone-anaesthetized dogs were encased in a lucite chamber as described by others⁴. The branches of the splenic artery and vein, which supplied the mucosal flap, were isolated, and all other vascular connections supplying the greater curvature of the stomach and the spleen were ligated. Each dog was heparinized (500 IU per kg), and the splenic artery was cannulated close to the mucosal flap and perfused (10 ml min⁻¹) with blood from a cannulated femoral artery with a constant flow roller-pump (Watson Marlow). Changes in perfusion pressure, indicating vascular resistance, were recorded with a transducer connected to the arterial blood line close to the stomach. Resting perfusion pressure was 80-100 mm Hg. Injection ports were sited in the arterial blood line, either close to the stomach (with a 3-s delay before reaching the stomach) or distally into a delay coil (allowing 30-s incubation in blood before the injected substances reached the stomach). Mean arterial blood pressure was measured via a cannula in a femoral artery and drugs could be administered intravenously (i.v.) through a cannula in a

Bolus injection of AA (25-200 µg intra-arterially (i.a.)) into the 30-s incubation coil produced a dose-dependent rise in gastric perfusion pressure, with 100 µg AA producing a nearmaximal increase of 56±9 mm Hg (mean±s.e.m. mean; 13 animals). This vasoconstriction was accompanied by localized blanching in the superficial mucosa and increased motility of the tissue within the chamber.

We investigated whether the increase in perfusion pressure induced by AA could be due to platelet aggregates blocking the microcirculation. Although some workers have shown that dog platelets do not aggregate when they form TXA2 from AA5

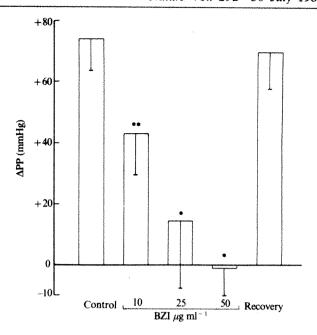

Fig. 1 Vasoconstriction in the canine gastric circulation by TXA₂ generated from arachidonic acid in blood, and its inhibition by 1-benzylimidazole in five dogs. AA (Grade I; Sigma) was stored in *n*-hexane (10 mg ml^{-1}) at $-20 \,^{\circ}$ C. After evaporation of the *n*hexane with N₂ from 1-ml aliquots, sodium hydroxide (0.5 M in methanol, 0.5 ml) was added and subsequently evaporated to dryness. The residue was dissolved (10 mg ml⁻¹) in 1 M Tris buffer (pH 10.5, 4°C), and stored in a light-proof container on ice. Control' represents response to AA (100 µg in 10-µl volume) injected i.a. into a delay coil so as to incubate with blood for 30 s before reaching the stomach. BZI (10-50 µg ml⁻¹ final concentration in blood) was infused i.a. (0.1 ml min) so as to incubate with blood 30 s before reaching injection site for AA. Results, shown as change in gastric perfusion pressure (ΔPP), are mean \pm s.e.m. of five experiments, where level of statistical difference from control (using paired data t-test) is shown as: *, P<0.05; **, P < 0.01.

infusions of very high doses of AA i.a. to the canine stomach, which elevate perfusion pressure⁷, may lead to thrombotic occlusion of the gastro-epiploic artery6. We have determined gastric arterio-venous (AV) differences in platelet counts in plasma after AA administration. Samples (2 ml) of blood collected in trisodium citrate (0.32%) were rapidly centrifuged in a modified Eppendorf bench centrifuge8 and the platelet count in the plasma determined in a Coulter counter. In four dogs, the AV platelet count after i.a. administration of 100 µg AA into the delay coil was not significantly (P > 0.05) different from that obtained without AA in control conditions, indicating that platelet aggregation with microemboli plugging of the gastric microcirculation is not a major factor in this vasoconstriction.

1-Benzylimidazole (BZI), like imidazole², is a selective inhibitor of TXA₂ formation in both human⁹ and dog¹⁰ platelets. To investigate its action, the hydrogen fumarate salt of BZI was dissolved in isotonic saline and infused into the delay coil so that it mixed with the blood for 30 s before reaching the AA injection site (thus incubating for 1 min in blood before reaching the stomach). In five dogs, BZI infusion (10-50 µg ml⁻¹, final concentration in the blood) alone had no effect on resting perfusion pressure in the gastric circulation. At 3 min after starting the infusion of BZI (10-50 µg ml⁻¹), the vasoconstrictor response to AA (100 µg into the delay coil) was dose-dependently reduced, presumably reflecting inhibition of TXA2 formation (Fig. 1). The BZI concentration reducing the vasoconstrictor response by 50% (13 µg ml⁻¹; 50 µM) is similar to that described for the inhibition of thromboxane formation from

Table 1 Effect of topical application for 1 h of acid (100 mM HCl) or acid (100 mM) plus sodium taurocholate (5 mM) either alone or during TXA₂-induced gastric vasoconstriction

AA was infused i.a. $(5 \,\mu\text{g ml}^{-1} \,\text{or}\, 50 \,\mu\text{g min}^{-1})$ into a 30-s incubation coil to generate TXA₂ for the latter 30 min of the study period. Results, which show the p.d., acid back-diffusion (ΔH^+) and lesion area of gastric mucosa over 1 h, are mean \pm s.e.m. of values from n degs. Significant differences from acid-alone group is shown by *, P < 0.05; **, P < 0.01.

 14 C-AA by canine platelets in vitro 10 . Infusion of BZI into the injection port close to the stomach failed to prevent the vaso-constrictor response to AA, indicating that the generation of TXA₂ was primarily in the blood and not in the stomach (Fig. 2). With 50 μg ml $^{-1}$ of BZI in the delay coil, a net vasodilator response to AA was observed in three of five experiments, suggesting that reduced TXA₂ formation in blood can unmask the biotransformation of AA to a metabolite, presumably prostacyclin 11 , which is a vasodilator in the stomach (Fig. 2). Indeed, even in the absence of BZI, close arterial administration of AA (100 μg), with only a 3-s delay before reaching the stomach, significantly (P < 0.01) reduced perfusion pressure (-23 ± 8 mm Hg, n = 8).

Within 3 min of terminating the BZI infusion to the incubation coil, the vasoconstrictor response to AA had returned to control values (Figs 1, 2). This system is thus useful for studying locally acting drugs without treatment of the whole animal.

The effect of a systemically administered cyclooxygenase inhibitor12 was also studied in six dogs. A low dose of indomethacin (25 µg per kg intravenously (i.v.)), given 5 min before injection of AA into the 30-s delay coil, significantly (P < 0.05) reduced the vasoconstrictor response (Fig. 3). With higher doses of indomethacin (50-500 µg per kg, i.v.) the vasoconstrictor response was converted into a vasodilator response, whereas with 1-5 mg per kg, i.v., indomethacin abolished all the vasoactive effects of AA. We conclude that low doses of indomethacin selectively inhibit the cyclooxygenase in platelets, thus reducing the formation of the vasoconstrictor, TXA2, while cyclooxygenase in the stomach retains its ability to transform AA into the vasodilator metabolite, prostacyclin. At higher doses, the cyclooxygenase in the stomach also becomes inhibited, with subsequent abolition of the vasodilator response. Such differential actions may explain the small vasodilation in

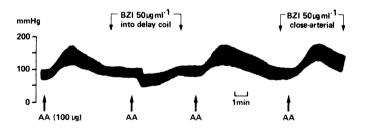

Fig. 2 Vasoconstriction in the canine gastric circulation induced by TXA₂, generated from AA (100 μ g in 10 μ l volume) injected into a 30-s delay coil. In this experiment, the vasoconstrictor response was converted to a vasodilator response when 1-benzylimidazole (BZI, 50 μ g ml⁻¹ final concentration in blood) was infused (0.1 ml min⁻¹) into the delay coil. BZI, infused locally to the stomach, failed to prevent the vasoconstrictor response to AA, indicating that TXA₂ was being generated in blood and not in the stomach.

the canine gastric circulation with infusion of high doses of AA after indomethacin pretreatment⁷.

As discussed previously for aspirin¹³, our present results in the dog suggest that indomethacin can selectively inhibit platelet cyclooxygenase *in vivo*. Whether such differential sensitivity would be of clinical value for the inhibition of platelet aggregation must await further studies as the more chronic administration of low doses of indomethacin may inhibit cyclooxygenase in most tissues. Previous studies with indomethacin at anti-inflammatory doses in rats did not reveal any selectivity between inhibitory effects on prostaglandin production in the inflammatory exudate and in the gastric mucosa (unlike sodium salicylate and the anti-inflammatory compound, BW755C) while the

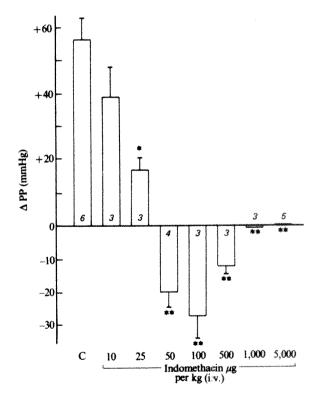

Fig. 3 Effect of indomethacin (10-5,000 μ g per kg) administered i.v. on the gastric vasoactive actions of AA (100 μ g; injected i.a. into a delay coil, so as to incubate with blood for 30 s before reaching the stomach). Indomethacin was dissolved in 5% w/v sodium bicarbonate solution, and the stock (20 mg ml⁻¹) diluted to desired concentration. Indomethacin in progressively increasing doses reduced the control (C) vasoconstriction with TXA2 generated from AA, and converted it into a vasodilator response, and subsequently abolished all vasoactive responses. Results, shown as increase or decrease in gastric perfusion pressure (Δ PP), are the mean \pm s.e.m. Number of animals used is shown in each bar.

* P < 0.02; **, P < 0.001.

inhibition of gastric cyclooxygenase was correlated with the production of gastric erosions¹

As mucosal ischaemia may be involved in the pathogenesis of gastric ulceration, we investigated whether the gastric vasoconstrictor actions of TXA2 could induce or enhance gastric damage. Although vasoconstriction induced in dogs by vasopressin alone does not induce marked erosion, it does potentiate the damage from topical application of a low concentration of bile salts4. We have therefore compared the gastric lesions after $1\ h$ topical application of acid (100 mM HCl) or acid plus the bile salt (100 mM HCl, 5 mM taurocholate) both alone, and during generation of the TXA₂ by infusion of AA (50 µg min⁻¹; 5 µg ml⁻¹ final concentration in blood) into the 30-s delay coil. This infusion produced a sustained increase in gastric perfusion pressure of 56 ± 7 mm Hg (n = 10), and is comparable with the AA concentration which generated TXA2 in dog blood, as detected by bioassay on vascular tissues3. In a randomized experiment in eight dogs, the acid back-diffusion (measured by titration) and electrical potential difference (p.d.) across the mucosa, indices of mucosal permeability15, were also determined in a two-compartment chamber.

Topical application of acid plus taurocholate for 1 h significantly increased acid loss and lowered p.d., but caused only slight gastric mucosal damage (measured in terms of lesion area with calipers) as shown in Table 1. Vasoconstriction induced by TXA2, generated from AA in blood, did not significantly alter acid back-diffusion or p.d. during application of topical acid, nor lead to observable damage (Table 1). However, in the presence of acid plus taurocholate, substantial damage of the mucosa was observed during vasoconstriction with TXA2. Necrosis and punctate bleeding became apparent within 10 min and large areas of the mucosal surface became damaged within 30 min (Table 1). After terminating the AA infusion, frank bleeding from the eroded surface was observed.

This work using TXA₂ confirms that vasoconstrictor agents can readily induce ulceration of the gastric mucosa in conditions where the mucosal surface had been in contact with low concentrations of bile salts^{4,16}. Although back-diffusion of acid alone into the mucosa seems to cause only slight gastric damage, concurrent vasoconstriction allows the accumulation of these back-diffusing hydrogen ions, leading to mucosal tissue acidification and thus necrosis. Our findings that the TXA2 generated from AA in blood is a powerful gastric vasoconstrictor and leads to extensive mucosal damage may implicate endogenous TXA₂ in the pathogenesis of gastric ulceration. Clinical conditions such as stress or shock might lead to local platelet activation with subsequent TXA2 generation in the stomach, or lead to an imbalance between prostacyclin-TXA2 levels, and hence induce gastric mucosal damage.

We thank Dr P. Thorogood for preparing 1-benzylimidazole and Dr J. R. Vane for helpful discussions.

Mobility of polypeptide chain in the pyruvate dehydrogenase complex revealed by proton NMR

Richard N. Perham & Harry W. Duckworth*

Department of Biochemistry, University of Cambridge, Tennis Court Road, Cambridge CB2 1QW, UK

Gordon C. K. Roberts

National Institute for Medical Research, The Ridgeway, Mill Hill, London NW7 1AA, UK

Recent studies of several small proteins by NMR spectroscopy and X-ray crystallography have clearly demonstrated significant internal mobility in their structures (see, for example, refs 1-9), which can involve not only amino acid side chains but also larger regions of polypeptide chain. Occasionally a plausible function for this mobility has been suggested 1,9, but there has been no conclusive evidence for a direct connection between intramolecular mobility and a defined step in an enzymatic mechanism. The pyruvate dehydrogenase (PDH) multienzyme complex of Escherichia coli (molecular weight (M_r) 4.5-6×10°) is one of the largest well defined assemblies of proteins known, comprising multiple copies of three different enzymes 10,11. The substrate is carried in thioester linkage by lipoyl-lysine residues of the lipoate acetyltransferase component, the structural core of the complex. The lipoyl-lysine residues act as swinging arms, carrying substrate between the catalytic centres of the three enzymes12-15 and between lipoic acid residues attached to different subunits in the lipoate acetyltransferase core 16-18. It has been conjectured that the lipoic acid-containing regions of polypeptide chain might be flexible 19,20 and therefore able to increase greatly the effective radius of a swinging arm¹⁹. We report here unexpectedly sharp lines in the 270-MHz proton NMR spectrum of the enzyme complex that are attributed to remarkable conformational mobility of large regions of polypeptide chain carrying the lipoic acid residues. This mobility would enhance the functional connection of active sites in a multisubunit structure.

A schematic mechanism of the PDH complex is shown in Fig. 1. A 270-MHz proton NMR spectrum of the intact complex is shown in Fig. 2a, the most striking feature of which is the appearance of several sharp resonance lines (between -0.6 and -3 p.p.m. from dioxan) attributable to the protein. The complex has an M_r of $\sim 6 \times 10^6$ (ref. 11), a diameter of at least 30 nm (refs. 10, 11) and a rotational correlation time of $\sim 10^{-5}$ s (ref. 14). A methylene proton moving with this correlation time would have a linewidth of \sim 8.5 kHz, and indeed there is an extremely broad envelope of resonance underlying the sharp lines in Fig. 2a. However, resonances with linewidths of only ~50 Hz must mean that some amino acid residues have substantial freedom to move rapidly with respect to the enzyme complex.

The most prominent sharp resonance in the spectrum is at -2.34 p.p.m., close to the positions of the methyl resonances of alanine (-2.32 p.p.m.) and threonine (-2.48 p.p.m.) in simple peptides. There is also a clear shoulder at -2.77 p.p.m., which is similar to the chemical shifts of the methyl protons of valine, leucine and isoleucine (-2.82 to -2.74 p.p.m.). Methyl groups in proteins are commonly found to rotate very rapidly about the carbon-carbon bond attaching them to the molecule^{1,2} However, this motion is not sufficient to explain the observed linewidths for these resonances. Rapid rotation of a methyl

Fig. 1 The reaction mechanism of the PDH multienzyme complex. E1 (pyruvate decarboxylase, EC 1.2.4.1), E2 (lipoate acetyltransferase, EC 2.3.1.12) and E3 (lipoamide dehydrogenase, EC 1.6.4.3) represent the three enzymatic activities. TPP, thiamine pyrophosphate; $R = CH_3 - ...$

group about this single axis can decrease the linewidth by no more than a factor of 4 (refs 21, 22) to give a predicted methyl linewidth of \sim 4 kHz in the present case—almost two orders of magnitude greater than that observed. It is clear that motion about several bonds must be involved, and that the sharp signals in Fig. 2a must arise from a region of the protein where the backbone, as well as the side chains, has substantial mobility.

It is impossible to integrate these spectra accurately owing to the obvious difficulties of drawing an appropriate baseline, but approximate integration of spectra obtained with a 5-s pulse interval indicates that several hundred protons per enzyme protomer contribute to the sharp lines in the spectrum. We define a protomer as 1/24th part of the enzyme complex, as the particle appears to be a 24-fold repeat of this structure, based on an E2 core of 24 polypeptide chains arranged with octahedral symmetry 10,11. Thus more than a few amino acids are involved and substantial regions of polypeptide chain must be mobile. The observed intensity ratio of the (Ala+Thr) to the (Val+ Leu + Ile) resonances is greater than would be expected from the amino acid composition of the complex (see refs listed in ref. 23), and in addition no sharp resonances from aromatic protons are observed. Clearly we are not observing a general mobility of all the polypeptide chains in the complex, but rather a high degree of mobility for specific regions of the primary structure

No change in the NMR spectrum was observed when the complex was converted to the acyl enzyme by treatment with pyruvate (0.11 mM), thiamine pyrophosphate (0.11 mM) and MgCl₂ (5.7 mM) in the absence of coenzyme A and NAD⁺ (see mechanism in Fig. 1). Likewise, no change was observed when the lipoic acid residues were reduced by treatment with NADH (0.15 mM) and NAD⁺ (0.05 mM) or when this reduced enzyme complex was acetylated by treatment with acetyl CoA (0.14 mM).

The PDH complex can be resolved into two subcomplexes: an E1-E2 subcomplex by selective removal of the E3 subunits in 4 M urea, and an E2-E3 subcomplex by selective removal of the E1 subunits at pH 10 (refs 24, 25). Both subcomplexes have a large M_r because they are based on the octahedral (24-chain) core of the E2 component. Their appearance on SDS-gel electrophoresis is shown in Fig. 3 and their proton NMR spectra in Fig. 2. The most prominent features of the spectrum of the intact complex are retained in the spectra of the subcomplexes. As the only type of polypeptide chain common to all three structures is that of lipoate acetyltransferase (E2), we infer that the most mobile regions of the intact PDH complex belong to this core enzyme.

The isolated E1 and E3 components are dimers, with M_r s of $\sim 200,000$ and 112,000 respectively¹⁹. Their proton NMR spectra (Fig. 4) differ from those of the intact complex and subcomplexes (Fig. 2), lacking the prominent (Ala+Thr) resonance at -2.34 p.p.m., but having clearly detectable resonances from aromatic protons. The lines in these spectra have apparent widths (~ 100 Hz) similar to those expected for molecules of this size^{1.26.27}, and there is no indication of substantial internal motion. These experiments, together with those on the subcomplexes, clearly implicate the E2 component as the source of the sharp resonances in the spectrum of the complex. Attempts to obtain a spectrum of the isolated E2 component were frustrated by its tendency to aggregate and precipitate at the high protein concentrations required.

Each E2 chain of the $E.\ coli$ complex contains two lipoic acid residues which become reductively acetylated by substrate (see Fig. 1) during the enzymatic reaction 16.17.28. Limited trypsin treatment of the complex releases fragments of the E2 polypeptide chain carrying these lipoyl groups, whereas E1 and E3 components remain bound to the residual part of the E2 core in an inactive complex which still has a very high $M_r^{19.20.29}$. This limited proteolysis suggested that the lipoic acid-containing

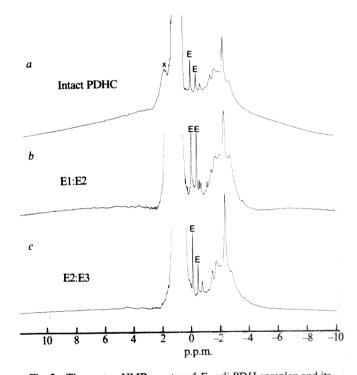

Fig. 2 The proton NMR spectra of E. coli PDH complex and its subcomplexes. Complexes were pelleted in the ultracentrifuge (3 h, 45,000g), dissolved in D₂O buffer, apparent pD 7.6, containing 20 mM potassium phosphate and 2 mM sodium EDTA, and dialysed exhaustively against the same buffer. Spectra were obtained at 270 MHz using a Bruker WH270 spectrometer. Quadrature phase detection was used, with a 6-kHz spectral width and 0.34-s pulse intervals. The free-induction decay was recorded in 4,096 data points and 2,000 decays were averaged. Before Fourier transformation, the free-induction decay was multiplied by an exponential corresponding to a line broadening of 5 Hz and the data table was extended to 8,192 points with zeros. Chemical shifts are expressed relative to internal dioxan. The peaks marked E arise from EDTA. a, Intact complex, 70 mg ml⁻¹; s_{20,w} (sedimentation coefficient corrected to water at 20 °C) of a portion of this sample, diluted to 3.0 mg ml⁻¹, was 58.7 S. The feature marked x is an instrumental artefact. b, E1-E2 subcomplex, prepared by resolution of intact complex on hydroxyapatite in 6 M urea, a method similar to that in ref. 24; 29 mg ml⁻¹. This preparation was a cloudy suspension which was not examined by analytical ultracentrifugation. c, E2-E3 subcomplex, prepared by treatment of intact complex at pH 10 according to refs 24,25; 57 mg ml⁻¹; $s_{20,w}$ at 3.0 mg ml⁻¹ = 30.9 \$.

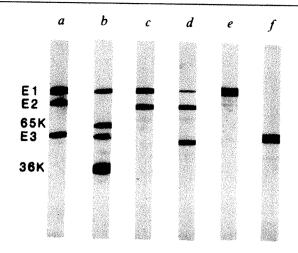

Fig. 3 Analysis by SDS-polyacrylamide gel electrophoresis of $E.\ coli$ PDH complexes and subcomplexes whose NMR spectra are shown in Figs 2 and 4. All samples were run on standard 7.5% gels in phosphate buffer 16. a, Intact enzyme complex; b, enzyme complex after limited digestion with trypsin and gel filtration on Sepharose 6B-CL 19; c, E1-E2 subcomplex prepared by removal of E3 subunits in the presence of 6M urea 24; d, E2-E3 subcomplex prepared by removal of E1 subunits at pH 10 (refs 24, 25); e, free E1 (dimers); f, free E3 (dimers). Fragments with apparent M, of 65,000 and 36,000 in e are tryptic products of the E1 and E2 chains, respectively 29.

regions of the lipoate acetyltransferase core protrude physically in the complex^{19,20,29}, and may form a 'fuzz' of lipoyl domains surrounding the E2 core in favourably oriented electron micrographs²⁰. The largest identifiable fragment containing lipoic acid residues has an apparent M_r of $45,000^{20}$ but this is rapidly broken down further by trypsin. Some degradation of the E1 chains from an apparent M_r of 100,000 to 65,000 is usually found and the E2 core is then composed of fragments of the E2 chain with an apparent M_r of 36,000, compared with an apparent M_r of 80,000 for the intact E2 polypeptide^{20,29} (see Fig. 3). Figure 4d shows the proton NMR spectrum of a trypsintreated complex, gel-filtered on Sepharose 6B to remove the lipoic acid-containing peptides¹⁹. All the sharpest peaks in the spectrum of the intact complex have disappeared, indicating that the proteolysis has removed the bulk of the highly mobile region or regions of the E2 chain. The spectrum of the tryptic core still contains resonances in the aliphatic region which are too narrow to arise from a rigid complex of this size, although they are much broader than the sharp components of the spectrum of the intact complex. They indicate the presence of regions of moderate internal mobility in the tryptic core.

The almost unfettered motion of the lipoyl groups revealed by ESR spectroscopy^{14,15} is accompanied by much conformational mobility of polypeptide regions of the lipoate acetyltransferase core that encompass the lipoyl-lysine residues. These are intrinsic properties of the enzyme protein and must not be confused with substrate-induced conformational changes. The chemical shifts of the sharp resonances in the NMR spectra are consistent with a random coil-like structure for the mobile regions, although some parts of these regions may have defined three-dimensional structures. Such structured regions near the lipoic acid residues might facilitate recognition by the enzyme active sites through protein-protein interaction.

Conformational mobility may explain some puzzling features of the enzyme complex. It might help to span the gaps between E1, E2 and E3 active sites¹⁹, which may be larger than a single lipoyl-lysine swinging arm could cover in a rigid protein³⁰⁻³², and it is presumably important in active-site coupling¹⁶⁻¹⁸. Several lines of evidence indicate that up to about half of the

lipoic acid residues of the *E. coli* PDH complex can be removed by limited proteolysis with trypsin²⁰ or inactivated by treatment with *N*-ethylmaleimide³³ without much loss of overall catalytic activity. The overall catalytic activity of the complex is directly proportional to its E1 content^{16,18,34} and the rate-limiting step in the mechanism must involve E1^{18,35}. Loss of catalytic activity would lag behind the loss or modification of lipoic acid residues if one lipoic acid residue could take over the role of another^{20,33,36,37}. Conformational mobility in the E2 core might facilitate this by allowing a given E1 active site to be visited by more than one lipoic acid residue, even a lipoic acid residue bound to a different E2 chain^{16,33,36}. The dihydrolipoyl group could in turn have a limited choice of E3 active sites at which to be reoxidized³⁸. That this mobility is vital in the functioning of the complex is reinforced by the observation (H.W.D., R. Jaenicke, R.N.P., G.C.K.R. and E. Wawrzynczak, unpublished)

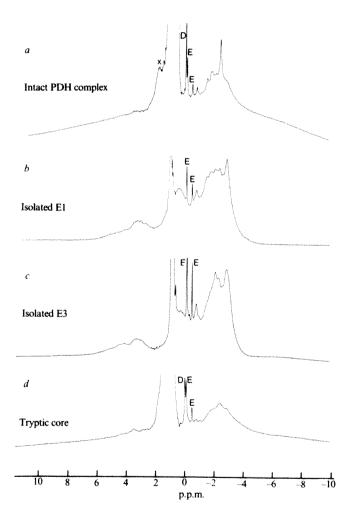

Fig. 4 The proton NMR spectra of some derivatives of $E.\ colin PDH$ complex. Protein samples were concentrated by ultracentrifugation (a,d) or ultrafiltration (b,c), and were then dialysed against the D_2O buffer and examined by NMR spectroscopy as described in Fig. 2 legend. The signal marked D in a and d is due to dioxan, ~ 1 mM, added as a reference; peaks E arise from EDTA; x is an instrumental artefact. a, Intact complex from Fig. 1. b, E1 component, obtained by the resolution procedure that yielded E2–E3 subcomplex (Fig. 2c); 51 mg ml $^{-1}$; $s_{20,w}$ at 3.0 mg ml $^{-1}$ = 9.65 S, as expected for the dimer, $M_r = 200,000$ (ref. 10). c, E3 component, obtained by the resolution procedure that yielded E1–E2 subcomplex (Fig. 2b); 12 mg ml $^{-1}$; $s_{20,w}$ at 3.0 mg ml $^{-1}$ = 6.03 S, as expected for the dimer, $M_r = 112,000$ (ref. 10). d, Core complex obtained by limited proteolysis of native PDH complex with trypsin and gel filtration on Sepharose 6B-CL, as in ref. 19; 66 mg ml^{-1} ; $s_{20,w}$ at 3.0 mg ml $^{-1}$ = 41.2 S.

that the PDH complexes of Bacillus stearothermophilus and ox heart and the 2-oxoglutarate dehydrogenase complexes of E. coli and ox heart all display very similar NMR spectra, indicating similar conformational mobility.

This work was supported in part by a research grant from the SRC (to R.N.P.). H.W.D. is a Travelling Fellow of the Nuffield Foundation. We thank Miss M. B. Thomas for technical assistance and D. Reed for performing the ultracentrifuge runs.

Delayed recruitment of maternal histone H3 mRNA in sea urchin embryos

Dan E. Wells, Richard M. Showman, William H. Klein & Rudolf A. Raff

Program in Molecular, Cellular and Developmental Biology, Department of Biology, Indiana University, Bloomington, Indiana 47405, USA

During the early stages of embryogenesis, the sea urchin embryo uses maternally synthesized mRNA stored in the egg as inactive messenger ribonucleoproteins (mRNPs)1. Release of this mRNA for translation allows the embryo to develop even in the absence of new mRNA synthesis. Comparison using twodimensional gel electrophoresis shows that the same spectrum of prevalent proteins are synthesized by eggs and zygotes 30-60 min after fertilization². Thus, unlike the case of the clam Spisula in which there are several prominent changes in translation associated with fertilization3, sea urchins have been thought to show little or no regulation of translation of specific mRNA sequences. Histone mRNAs are major components of the mRNA pool, comprising as much as 4-8% of the total mRNA of eggs4, yet their products, histones, would not normally be detectable on two-dimensional gels. We report here that mRNA complementary to a histone H3 cloned probe remains in the inactive mRNA pool for 90 min after fertilization before it begins to be translated. This is long after the rapid increase in overall protein synthesis, using stored mRNAs, has begun. As we can demonstrate no significant synthesis of histone H3 mRNA during this period, stored histone H3 mRNA must be subject to sequence-specific translational regulation.

Patterns of protein synthesis during early sea urchin embryogenesis have supported the idea of a rapid linear release of stored maternal mRNA from the mRNA pool. The kinetics of protein synthesis require that the release of stored mRNA for translation starts 2 min after fertilization⁵. This rapid initiation of the release of stored mRNAs is further indicated by the kinetics of recruitment of free ribosomes into polysomes (Fig. 1). Whether measured by optical density or by use of a ribosomal RNA-specific cloned probe, recruitment starts immediately after fertilization and proceeds in a linear manner for ~90 min before reaching a plateau at 20-25% of the available rRNA. In

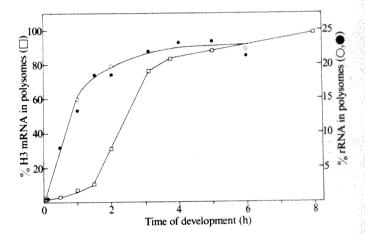

Fig. 1 Time of appearance of rRNA and histone H3 mRNA in the polysomes of S. purpuratus embryos. Embryos were cultured at 13.5 °C for the appropriate lengths of time and polysomes were prepared by the procedure of Wold et al. 10, omitting the polysinyl sulphate. Material was layered on to 5-40% exponential sucrose gradients and centrifuged for 2.5 h, 26,000 r.p.m. in an SW27 rotor. Individual fractions were collected, deproteinized with phenol/chloroform/isoamyl alcohol (25:24:1) and RNA precipated with ethanol. RNA samples were taken up in 1×MOPS buffer (20 mM morpholinopropane sulphonic acid, 5 mM sodium acetate, 1 mM EDTA) at pH 7.0, 6% formaldehyde and 50% formamide, heated at 65 °C for 5 min, cooled rapidly and electrophoresed on a 1% agarose gel in 1 × MOPS buffer containing 6% formaldehyde. After electrophoresis the gel was soaked for 30 min in 20 × SSC (1 × SSC = 0.15 M NaCl, 0.015 M sodium citrate, pH 7.4), and blotted on to a nitrocellulose filter in 10×SSC. The filter was rinsed with 3×SSC and baked for 2 h at 80 °C in a vacuum oven. Probes for histone H3 (p3H1, provided by L. Kedes) and rRNA (pLv 60, provided by D. Stafford) were nick-translated to $1-5 \times 10^7$ c.p.m. μg [α-32P]dCTP. Filters were prewashed in 10×Denhardt's solution (0.02% bovine serum albumin, 0.02% Ficoll, 0.02% polyvinyl pyrolidone), 0.1% SDS, 0.02 M phosphate buffer, $5 \times SET$ ($1 \times SET = 0.15$ M NaCl, 0.025 M Tris, pH 8.0, 0.002 M EDTA) at 68°C for 1-2 h. The filters were prehybridized at 45°C in 10 ml of 10% dextran sulphate, 5×SET, 0.02 M phosphate buffer, 1×Denhardt's, 100 µg ml⁻¹ sheared calf thymus DNA. 100 μ g ml⁻¹ poly (rA) and 50% formamide. After 1-2 h, 1-5 × 10⁷ c.p.m. of nick-translated plasmid was added and hybridized at 45 °C for 12-16 h. After hybridization, the filters were washed at 68 °C for 1 h in each of the following: (1) $5 \times SET$, 0.1% SDS, 0.1% sodium pyrophosphate and 0.025 M phosphate buffer; (2) $1 \times SET$, $1 \times Denhardt's$, 0.1% sodium pyrophosphate phate and 0.025 M phosphate buffer; (3) 0.3 × SET, 0.025 M phosphate buffer, 0.1% sodium pyrophosphate, 0.1% SDS. The filters were air dried and exposed to preflashed 11 Kodak X-Omat RPfilm at -70 °C using Dupont Cronex lighting plus intensifier screens. Exposure times ranged from 2 to 96 •, % rRNA in polysomes as determined by A253; O, % rRNA in polysomes as determined by hybridization with rDNA probe pLv60; □, % of histone H3 mRNA in polysomes

addition, titrations with labelled poly(U) show that >70% of the total cytoplasmic poly(A) is present in the polysomes of 2-h-old embryos, while <5% is found in polysomes of unfertilized eggs⁶.

To determine whether H3 mRNA is recruited with the same kinetics as total mRNA, we have measured the relative amount of H3 mRNA present in the mRNA and polysome compartments of the embryo from fertilization through 8 h of development. Strongylocentrotus purpuratus embryos were cultured for specific times and the polysomes displayed on 5-40% exponential sucrose gradients. After fractionation the RNA was extracted, electrophoresed on agarose gels and blotted on to nitrocellulose filters. The filter-bound RNA was then hybridized to a ³²P-labelled nick-translated clone containing only the coding sequence for histone H3. The amount of probe hybridizing to each region of the gradient gave a direct measure of the percent of H3 mRNA found in the polysomal and mRNA compartments of the embryo at a given time (Fig. 2a, c). Quantification was done by densitometric scanning of autoradiographs exposed within the linear range of the film. To ensure that the detected RNA was polysomal, parallel experiments were performed using EDTA to dissociate polysomes (Fig. 2b, d).

At 90 min after fertilization, <10% of the total hybridizable H3 mRNA is found in the polysomal region of the gradient (Fig. 1). Between 90 min and 4 h there is a rapid linear rise in the per cent of the total H3 mRNA in the polysomes until, after 4 h, >85% of the H3 mRNA is detected in the polysome region of the gradient. Whether embryos are cultured in the presence or absence of actinomycin D, we can detect no significant increase in the amount (per µg of total RNA) of H3 mRNA during the first 5 h after fertilization (Fig. 3). This, in conjunction with the recruitment data in Fig. 1, suggests that little of the H3 mRNA initially present in the egg remains in the masked state. Newly synthesized H3 mRNA begins to accumulate measurably 6-8 h after fertilization, and seems to move rapidly into the polysomal fraction, as by 8 h >95% of the H3 mRNA is present in polysomes. In contrast to H3 mRNA, α-tubulin mRNA does not exhibit the 90-min delay, but is significantly loaded by 30 min after fertilization (data not shown).

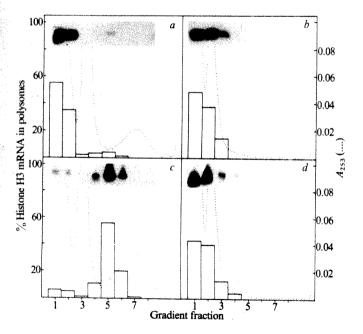

Fig. 2 Autoradiographs and quantification of representative H3 mRNA titration from 1-h and 3.75-h embryos. The amount of probe hybridizing to each fraction of the gradient is expressed as the percentage of the sum of the probe hybridized in all fractions. A_{253} (.....) was obtained using an Isco UA5 absorbance monitor. Fractions were collected from the top. a, 1-h embryos; b, 1-h embryos, EDTA released; c, 3.75-h embryos; d, 3.75-h embryos, EDTA released.

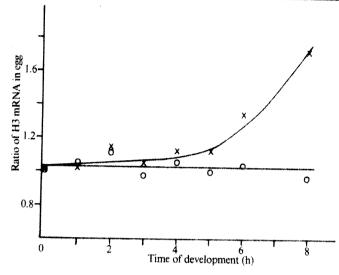

Fig. 3 Titration of total H3 mRNA from unfertilized egg through 8 h of development in the presence or absence of actinomycin D. Embryos were cultured in the presence of 25 µg ml⁻¹ actinomycin D. At each time point, identical aliquots were removed and the total RNA extracted, electrophoresed, blotted and hybridized as described in Fig. 1 legend. Data are given as the ratio of the amount of H3 at each time point to the amount in the unfertilized egg. x, Control; O, actinomycin D.

Consistent with these results is a recent study of in vitro translation of sea urchin mRNA using a cell-free system derived from sea urchin eggs. This study shows that histone H3, as well as other histones, are synthesized in vitro in significant amounts; however, very little histone synthesis was observed in vivo until at least 1 h after fertilization7. Our data show that this delay in appearance of histone H3 is to be expected from the behaviour of the H3 mRNA. Because most mRNAs in the egg must be unmasked before translation can occur8, the delay in H3 mRNA recruitment may be due to a specific delay in unmasking of histone mRNAs. Alternatively, the delay may be due to a change in initiation properties of ribosomes or the lack of a histone mRNA-specific translation factor. We cannot yet discriminate between these possibilities. Woods and Fitschen⁹ have observed changes in histone mRNA distribution in sea urchin polysomes during telophase of the first cleavage cycle and suggest that it may be associated with the onset of DNA synthesis. However, the absence of any further association of use of histone mRNA with the cell cycle argues against a direct causal association between DNA synthesis and histone mRNA recruitment. The marked contrast between the recruitment of H3 mRNA and that of most maternal mRNAs clearly demonstrates translational regulation of early embryonic protein synthesis in the sea urchin embryo.

BOOK REVIEWS

In pursuit of a self-conscious science

J. O'Keefe and P.D. Wall

FOR the half-century between 1920 and 1970, most neurophysiologists and experimental psychologists were content to leave "consciousness" outside the boundaries of their disciplines. The properties traditionally attributed to consciousness—freedom of the will, creativity, self-knowledge—seemed difficult, if not impossible, to capture within the accepted notions of deterministic science. Furthermore there was a strong reaction to the use of consciousness as an explanatory device: two actions were different because one was voluntary; two stimuli differed because one was attended to.

In recent years this radical behaviourist approach has been modified and recent work has thrust the problem of consciousness to the forefront again. One scientist who deserves considerable credit for insisting on a place for consciousness in neurophysiology during this scientific dark night of the soul is the author of the book under review. In 1953, Sir John Eccles published a book entitled Neurophysiological Basis of Mind (Oxford University Press) which was quite the best summary up to that time of how nerve impulses pass from one cell to another. Having been for many years one of the main proponents of the electrical synapse theory. Eccles accepted the new evidence for the chemical synapse and became one of the architects of our modern understanding of neuronal transmission, for which work he received the Nobel prize in

In 1953 virtually no aspect of brain research had a direct bearing on the question of consciousness and Professor Eccles's inclusion of a final chapter on this topic was regarded as a mild eccentricity. Consciousness entered the scientific picture as a subtle force operating at the level of the indeterminate synapse. Eccles's preoccupation with the brain-mind problem has increased over the years: the last chapter of the 1953 book has become the first chapter of the present book. The book is divided into three sections. The first section (Lectures 1 and 2) sets out Eccles's current theory of the mind which he has developed in association with the philosopher Sir Karl Popper. The second (Lectures 3-6) describes recent experiments in neurophysiology and psychology which bear on the question of consciousness, and the third (Lectures 7-10) marks a shift to a consideration of

The Human Psyche. The Gifford Lectures, University of Edinburgh 1978-1979. By John C. Eccles. Pp.279. ISBN 3-540-09954-9. (Springer-Verlag: 1980.) DM44, \$26.

the broader issues of the relation between consciousness and social values.

Eccles's theory of consciousness views it as an entity which exists independently of the brain but which interacts strongly with it. He rejects materialist theories which identify consciousness with the activity of a part or all of the brain. The brainconsciousness interaction takes place at the level of the cerebral cortex which unfortunately does not have the appropriate anatomical structure. Whereas consciousness appears to be a unity which maintains its integrity and continuity over time, the cerebral cortex consists of numerous, relatively independent modules each coding for a different aspect of the sensory environment or motor behaviour. Eccles concludes that "... the unity of conscious experience is provided by the self-conscious mind and not by the neural machinery of the liaison areas of the cerebral hemisphere" (p.50). How is this accomplished?

... the self-conscious mind can scan the activity of each module of the liaison brain or at least those modules tuned in to its present interest... the self-conscious mind has the function of integrating its selections from the immense patterned input it receives from the liaison brain... in order to build its experiences from moment-to-moment [p.46].

It would appear that on this formulation the problem of consciousness is inaccessible to neurophysiological analysis and perhaps to any scientific analysis. It is a non-neural entity with its own structure, interests, expectations and creative impulses, attributes which are never discussed but which are constantly invoked to "explain" psychological and physiological findings.

Much of the middle section of the book is an excellent description of recent findings. As might be expected from the author's preoccupation with the cerebral cortex as the part of the brain which liaises with the self-conscious mind, much (and by far the most satisfactory part) of this section deals with effects ascribable to the cortex. Visual illusions show that much of the sensory world is created by the brain

from inadequate data; EEG recordings of the brain potentials from the scalp show that cortical activity precedes voluntary movements and accompanies anticipated stimuli. Unfortunately, these fascinating findings are "explained" by hand-waving references to the self-conscious brain. Since the "explanation" is given in terms of a world with normal scientific rules, one may reasonably ask for experiments to investigate this world, but as we approach it retreats as a will'o the wisp.

Subsequent chapters give a cursory but adequate account of the limbic system, the pain system and the reticular activating system of the brainstem. Professor Eccles acknowledges that these may have some bearing on the problem of consciousness but keeps his sights firmly fixed on the cerebral cortex. A surmise in the section on the limbic mechanisms of emotion "that Gary Gilmour, the last criminal to be executed in the United States, may have been suffering from amygdaloid seizures" (p.116-117) warms us of what to expect in the third and final section of the book: the relation between brain, consciousness and social values.

This last section contains a wide ranging set of comments and quotations on topics centred around the twilight area where scientific ideas impinge upon social values. Professor Eccles is particularly severe on scientists who would reduce human action or human values to mechanistic explanations. The sociobiologist E.O. Wilson who seeks to explain altruistic behaviour on the basis of selfish genes and the molecular biologist Jacques Monod who seeks to emphasize the chance elements in human existence come in for special opprobrium. Although some cogent arguments are advanced, much of the discussion takes the form of poetic quotations from suitably authoritative sources: Sherrington, Planck, Heisenberg. Eddington and Einstein. We suggest that most readers will take these last chapters for what they are: the personal prejudices of a great neurobiologist who has strayed outside the bounds of his area of expertise. We hope it won't deter them from giving serious consideration to the earlier chapters.

J. O'Keefe and P.D. Wall are members of the Cerebral Functions Research Group at University College, University of London.

A tool of elegance and great power for physicists...

Peter McClintock

Green's Functions and Condensed Matter. By G. Rickayzen. Pp.357. ISBN 0-12-587950-4. (Academic: 1980.) £22.80, \$55. Many-Particle Physics. By G.D. Mahan. Pp.1,003. ISBN 0-306-40411-7. (Plenum: 1981.) \$85, £53.55.

WHEN George Green, miller and part-time theoretical physicist, died in 1841 at the early age of 47 the Nottingham Review commented regretfully that "... had his life been prolonged, he might have stood eminently high as a mathematician". Little did they realize. During his brief but remarkably productive twelve-year spell of scientific activity, starting with An Essay on the Application of Mathematical Analysis to the Theories of Electricity and Magnetism (published privately in 1828), Green had introduced the concept of electric potential, had carried out work of fundamental importance in wave theory and hydrodynamics and had laid the foundations for modern theories of elasticity. Notwithstanding this substantial contribution, however, and despite his acknowledged influence on both Stokes and Kelvin, Green's memory remained relatively obscure until more than a century after his death, when R.P. Feynman took up some of the techniques introduced by Green, and developed them for application to nuclear physics and the theory of elementary particles. The use of Green's function methods has subsequently spread through the rest of physics including, particularly, solid state physics.

Thus it has come about that no physicist in the 1980s can remain indifferent to Green's functions. For those who love them including, probably, the majority of theorists, Green's functions constitute a tool of elegance and great power, indispensable in some areas of physics, which can with advantage be applied to almost any problem with which they may be confronted. Others regard them with profound suspicion. They feel that devotees frequently employ Green's function techniques for their own sake, for the sheer joy of using them, and often at the expense of physical insights which can more readily be gained through simpler approaches. Their mistrust probably relates, at least in part, to a lack of understanding. The publication of two new advanced textbooks on the subject, each aimed at filling what has been an unfortunate lacuna in the literature, is therefore to be applauded.

The similarities between G. Rickayzen's Green's Functions and Condensed Matter and G.D. Mahan's Many-Particle Physics are greater than their differences. Both books are aimed at advanced graduate students, or academic staff, and both assume a good prior knowledge of quantum mechanics at the level provided.

say, by the classic texts of Schiff or Landau and Lifshitz. They are both most definitely books of physics, as opposed to mathematics, each consisting very largely of an account of how Green's function and Fevnman diagram techniques can be applied in practice to a selection of topics in solid state physics. Both books cover, for example, phonons, the Coulomb gas, electron-phonon interactions, transport theory, linear response, superconductivity and liquid helium (which by tradition is treated as solid state physics). Both provide, for each chapter, references to the original literature (Mahan's being the more extensive) and a set of problems, without solutions. In each case, the standard of production is high. The most obvious difference between the two books lies in their respective lengths: Rickayzen's has 357 pages in total whereas Mahan's, with 1,003, is almost three times as long. Much of this difference can be accounted for in terms of Mahan's detailed treatment of certain topics - for example, optical properties or polarons — which Rickayzen either omits or treats less fully; but, to a considerable extent, it also relates to their very different styles of presentation.

Mahan's stated objective was

... to take standard subjects ... and to summarize what is generally known. All the steps are retained in the derivation, so that the answers are obtained by starting from the beginning and working through to the end.

This latter feature is quite unusual in advanced texts, which commonly leave the reader to fill in a lot of the intermediate steps for himself, and it is a reflection of Mahan's declared intention of producing a book which graduate students will be able to use on their own, if necessary, in the

absence of a formally taught course. It will also be a considerable help and encouragement to the less theoretically biased readers at all ages and stages. Mahan writes in a style which is relaxed without being imprecise, and which often displays refreshing candour as, for example, in relation to the ground state properties of quantum fluids where he comments that, unusually, "... the Green's function method gives awful results".

Rickayzen's book, which starts disarmingly with the truism that "Anyone who has used the Coulomb potential due to a point charge has used a Green's function", is by contrast a model of brevity and succintness. The most immediate benefit lies in the remarkable range of topics which he has managed to treat at a useful level in the space available: in addition to the items mentioned above. the book also includes chapters on magnetism, disordered systems and critical behaviour. The relatively condensed presentation should be well suited to the graduate student in theoretical physics at whom the book is primarily aimed, particularly if used to support and supplement the material provided in a formal course of lectures on the subject.

Each of these books is excellent in its own way. They should be a real help both in educating the next generation of solid state theorists and also in rendering "Greenery" just a little bit less daunting to those professional physicists who have not yet fully come to terms with the power and utility of these techniques.

Peter McClintock is a Senior Lecturer in the Department of Physics, University of Lancaster.

... and another for molecular biologists

Ueli Schibler

Genetic Engineering 1. Edited by Robert Williamson. Pp.168. ISBN 0-12-270301-4. (Academic: 1981.) £9.80, \$24.

GENETIC engineering has not turned dull molecular biologists into imaginative ones. There is, however, little doubt that both could profit immensely from this elegant and powerful technique. This is enough justification for a new series entitled *Genetic Engineering*. According to the editor, the purpose of the new periodical is to rapidly publish comprehensive reviews about different aspects of recombinant DNA technology. This first issue addresses a very heterogeneous readership, including students, experienced researchers and physicians. It brings together a rather technical article about cDNA cloning, an

article about prenatal diagnosis of abnormal haemoglobin genes and a review on transcription of cloned genes in different experimental systems.

J. E. Williams provides a meticulous account of every aspect of the applicability and feasibility of cDNA cloning, and evaluates most of the tricks used in the enzymatic construction of recombinant molecules containing cDNA and their propagation in bacterial host cells. Particularly helpful are the discussions of mRNA complexity and the size of a cDNA library. Using this information one can easily calculate how many bacterial colonies should be screened to obtain, with a certain probability, an mRNA sequence of a given abundance. It is a pity that Williams did not include a short protocol

which he has found to be generally applicable. This might have reduced the beginner's confusion over choosing the most appropriate procedures, since he has just read 55 pages describing alternative methods, loop-holes and pitfalls.

The second article deals with a medical application of recombinant DNA technology. P. F. R. Little summarizes the lesions of haemoglobin genes associated with different haemoglobin deficiencies and how they can be detected by Southern blotting of DNA from fetal cells obtained by amniocentesis. Two major principles are discussed: the first is direct demonstration of deletions within a globin gene itself; this approach is particularly valuable for certain thalassaemias. The second is based on the fact that deficient genes are often linked to polymorphism of nearby restriction endonuclease sites, which in turn is readily detectable. This approach can be applied to any disfunctional gene where linkage exists, and does not depend on the nature of the lesion in the DNA. As, thanks to molecular cloning technology, our knowledge about genes increases rapidly, the antenatal diagnosis of lesions at the DNA level will certainly have an important future in preventive medicine.

Several systems to study the expression of cloned genes either in vitro or in vivo have recently become available. Two of them, the transcription of isolated genes in microiniected oocytes, and in cell-free extracts, are reviewed in an authoritative article by M. P. Wickens and R. A. Lasky. Most of the important published work carried out on the expression of eucaryotic genes in these systems is critically reviewed and put into perspective. In vitro transcription of genes, both wild type and after mutation in vitro, has been important in recognizing signals on DNA. This strategy succeeded in defining promotors for various genes transcribed by RNA polymerase III, and sequence elements in genes transcribed by RNA polymerase II. which are required for correct initiation and modulation of transcription.

All three articles of the first issue of Genetic Engineering are well written and certainly worth reading. It seems to me that the articles which are published in this issue and are planned for publication in further issues could have been grouped more logically, for example by putting the construction of cDNA (this issue) and genomic DNA recombinants (planned for a future issue) into the same volume. The same holds true for Wickens and Lasky's article and the planned article on expression of cloned genes in transfected cells. However, if the promised publishing strategy is adhered to, the series should quickly build into a useful reference work on recombinant DNA technology.

Ueli Schibler is a Junior Staff Member at the Swiss Institute for Experimental Cancer Research, Lausanne.

Isolation and assay of insect hormones

H. F. Nijhout

Neurohormonal Techniques in Insects. Edited by Thomas A. Miller. Pp.282. ISBN 3-540-90451-4. (Springer-Verlag: 1981.) DM79, \$46.70.

If it is possible to pinpoint the birth of a biological discipline, then neuroendocrinology was born in 1917 when a Polish biologist, Stefan Kopeč, reported that the brain of gypsy moth caterpillars produced a hormone that stimulated pupation. The hormone he discovered we now call prothoracicotropic hormone (PTTH), because it stimulates the prothoracic glands to secrete the moulting hormone, ecdysone. In the decades that have passed since this landmark discovery, the recognition, isolation and identification of additional insect neurohormones has proceeded at a slow but steady pace and Neurohormonal Techniques in Insects provides an account of the current status of these endeavours.

The purpose of this volume is to provide a compendium of the methods that are currently used by various laboratories to collect, assay and purify the neuroendocrines of insects. The book is divided into 11 chapters dealing with as many neuroendocrine factors, to wit: proctolin; adipokinetic hormone; diuretic hormone; insulin- and glucagon-like hormones; bursicon; pupariation factors; cuticle plasticizing factors; eclosion hormone; diapause hormone and PTTH. Each chapter has a brief introduction establishing the biological properties of the hormone in question, followed by a review of various bioassay methods and finally a detailed description of the methods used in its isolation and characterization.

The first two chapters by Staratt and Steele and by Stone and Mordue on the isolation and identification of proctolin and adipokinetic hormone, respectively, are by far the best methods papers I have ever seen. The quality of the remaining contributions is, predictably, variable both in method of exposition as well as in the skill with which various problems are handled. Some of the defects become understandable, though, when one considers the enormous obstacles that must be overcome by those who discover a new hormone and venture to identify it. The numbers of insects that need to be worked up to extract a sufficient quantity of hormone are truly prodigious. For example, 125,000 cockroaches yielded 1.12 mg of proctolin, and fractionation of 96,000 silkworm heads yielded 3 mg of a heterogeneous residue possessing high PTTH activity. To make matters worse, the bioassays that must be used are cumbersome and consume vast quantities of time, manpower and hard-won hormone. The biggest problem, though, is that the specificity of a bioassay for a given

hormone is often questionable, and I found a critical consideration of what constitutes an optimal assay method and scoring procedure lacking in most chapters.

A budding biochemist should have no difficulty in following the rationale as well as the procedures employed by the various authors and it should be possible for any well equipped laboratory to employ the methods described to attempt their own hormone isolations. However, it is evident from the accounts in this volume that the development of reliable, and preferably biochemical, assays should be the first order of business for the future.

H. F. Nijhout is Associate Professor of Zoology at Duke University, Durham, North Carolina.

Creative catalysis

G.W. Parshall

Homogeneous Transition-metal Catalysis: A Gentle Art. By Christopher Masters. ISBN hbk 0-412-22110-1; ISBN pbk 0-412-22120-9. (Chapman & Hall: 1980.) Hbk £20, \$25; pbk £9.50.

THE gentle art described in this book is the synthesis of organic compounds through the skilful application of transition metal complexes as catalysts. Dr Masters' purpose in writing this book was to stimulate enthusiasm for this art. He succeeds admirably because he has produced not just a readable description of the subject as it exists today but also a perceptive analysis of developing research areas

In the introductory chapter, Dr Masters describes the basic principles of bonding and reactivity in transition metal complexes in simple terms for the non-specialist. Phenomena such as oxidative addition, β -elimination and steric and electronic effects are illustrated with significant examples. The fundamentally kinetic nature of catalysis is stressed.

The heart of the book is a description of homogeneous catalysis as it is practised today. Fourteen of the two dozen or more major commercial applications of soluble transition metal catalysts are discussed in some detail. The processes described include the reactions of carbon monoxide with acetylenes, olefins and alcohols, the dimerizations of olefins and dienes, and the oxidations of several different types of hydrocarbons. Fundamentally organometallic processes such as the hydrogenation, isomerization, polymerization and metathesis of olefins are also included, even though industry usually chooses heterogeneous catalysts for these

operations. Some significant reactions like the hydrocyanation and hydrosilylation of olefins are omitted and others are simply mentioned. However, the reactions that are included are discussed expertly and with sufficient detail to satisfy the reader who is just becoming acquainted with the field.

The book closes with analysis of research trends in homogeneous catalysis. Nitrogen fixation, C-H bond activation and CO hydrogenation are cited as well-studied areas in which the crucial discoveries have yet to be made. Other topics such as bimetallic catalysis are suggested as profitable areas for research.

Homogeneous Transition-metal Catalysis will probably be used largely as a reference or introductory text for the

industrial chemist working in this field. It may also be used in teaching graduate-level courses in catalysis or organometallic chemistry. The emphasis on understanding and on research should appeal to the student.

Dr Masters has succeeded nicely in his objective to convey enthusiasm for homogeneous catalysis. It is a dynamic subject from both scientific and practical viewpoints and this emerges clearly from the text. The reader should be both stimulated and informed by perusal of this book.

G.W. Parshall is Director of Chemical Science in the Central Research and Development Department of E.I. du Pont de Nemours & Co., Wilmington, Delaware. His most recent book is Homogeneous Catalysis (Wiley, 1980).

Illumination on the light reactions

J. Barber

Photosynthesis: Physical Mechanisms and Chemical Patterns. By Roderick K. Clayton. Pp.275. ISBN hbk 0-521-22300-8; pbk ISBN 0-521-29443-6. (Cambridge University Press: 1981.) Hbk £17.50, \$32.50; pbk £6.95, \$11.95.

CONSISTENT with Roderick Clayton's outstanding talents as a scientist and author, I judge this, his latest book, as being first class. He has written a lucid and well-structured text which makes marvellous reading for the expert and also will satisfy the requirements of nonspecialists and students. He achieves this. in part, by "digressions" and by giving background "notes" in an appendix. The overall effect is to pass on the excitement of an active scientist who, with the qualities of a talented teacher, instinctively takes the reader through logical developments calling on the basic laws of photophysics, photochemistry and thermodynamics wherever necessary.

From the title it is clear that Clayton has concentrated on the "light reactions" of photosynthesis and consequently has restricted his discussion of carbon fixation (the "dark reactions") to one short chapter at the end of the book. It is inevitable that in producing a modern text on the light reactions of photosynthesis he should not only deal with oxygen-evolving organisms, but also with photosynthetic bacteria. The book has been divided into four distinct parts, each consisting of several chapters. Part I gives a historical account which introduces the reader to the basic concepts of the light reactions, including the nature and properties of the pigments and the existence of different types of photosystems. Part II then concentrates on the organizational aspects, while Part III deals with the photochemistry and associated transfer of electrons and protons. Part IV

is concerned mainly with photophosphorylation. At the end of each chapter the author has listed a few selected references for further reading. Also, the background notes in the appendix cite other key work.

Without any hesitation, I thoroughly recommend this book to specialists and non-specialists alike who have an interest in the more biophysical aspects of photosynthesis, whether it be from the research or the teaching point of view. I also think that those working in other areas of photobiology may find much of the basic substance of the book useful.

J. Barber is Professor of Plant Physiology in the Department of Pure and Applied Biology, Imperial College, University of London.

Medical malacology

Frank J. Etges

Freshwater Snails of Africa and their Medical Importance. By David S. Brown. Pp.487. ISBN 0-85066-145-5. (Taylor & Francis, London/American Malacologists Inc., Melbourne, Florida: 1980.) £25, \$55.

DAVID Brown is to be congratulated on writing an exceptionally fine treatise on the gastropod fauna of Africa, a reference book which will be set a standard of quality and content for many years. His stated goal of presenting a "comprehensive" account of this subject which will be of value to specialists and students of taxonomy, medical malacology and freshwater biology has surely been attained. This achievement is a tribute both to the broad experience of the author, and to the abilities of his many acknowledged

colleagues and consultants. Written by a single author, the book's structure and style are unified and integrated to a degree that multi-author publications rarely achieve.

Brown divides his subject matter into 12 chapters, two of which form essentially the first half of the book and provide a systematic synopsis of African freshwater snails; two short chapters cover snail-borne parasites of medical and veterinary importance in Africa, and the remainder deal with ecological, physiological and biogeographical aspects of snail biology, stressing snail hosts of schistosomes and approaches to snail population control.

The synopsis of more than 300 gastropod species is efficiently and accurately presented, including carefully documented descriptions of morphological and ecological characteristics, plus (usefully) a brief statement of their parasitological importance as real or potential intermediate hosts. The text is thoroughly illustrated with 128 photographic plates, line drawings and distribution maps, all arranged to maximum advantage. Here, as in all chapters, a comprehensive, wellselected citation of literature stresses work done in Africa or on material of African origin; inclusion of a large number of contributions from publications in southern Africa will be of special interest to readers unfamiliar with the volume and quality of this body of literature.

The two chapters on snail-borne parasites of medical and veterinary importance concentrate on snail-parasite interrelationships. The account of snails and schistosomes is, justifiably, given prominence since the impact of schistosomiasis on human beings is so great, and because so much more data is available for discussion of this complex. One deficiency in this section is the omission of the human disease, heterophyosis (admittedly referred to in the systematic description of its snail host, Pirenella), in favour of veterinary parasites such as paramphistomes, and a potentially occurring human disease, angiostrongylosis. Overall, I felt that the parasitological section was disappointingly brief, seeming as it did to be included as a kind of (unnecessary) justification for the rest of the book.

The remaining six chapters on ecological, physiological and biogeographical aspects of African snails are excellent; particularly outstanding is that on the biology of the genus *Bulinus*, a subject of great complexity and interest to biomedical scientists. Completing the book are a unique appendix, in which major methods of field and laboratory studies of snails and parasites are presented, and taxonomic and general subject indexes; I found the latter extremely useful and accurate, and reflective of the general editorial excellence of the book.

Frank, J. Etges is Professor of Parasitology at the University of Cincinnati.

UNIVERSITY OF OXFORD

NUFFIELD DEPARTMENT OF PATHOLOGY AND BACTEROLOGY

TECHNICIAN (MICROBIOLOGY)

Technician required for preparation of class material for course in clinical microbiology. Duties will include assistance in research projects. The successful applicant will be offered training in diagnostic microbiology. Candidates should possess a degree in biological sciences or qualifications suitable for admission to courses leading to the special examination of the Institute of Medical Laboratory Sciences. Preference will be given to persons with training or experience in medical microbiology. Salary will be on the Whitley Council scale for Medical Laboratory Scientific Officers (£4,677 to £6,597) depending on qualifications and experience.

Applications, including curriculum vitae and the names of two referees to Dr M P E Slack, Department of Bacteriology, Level 7, John Radcliffe Hospital, Headington, Oxford OX3 9DU, from whom further details may be obtained. Tel: Oxford (0865) 64711 Ext 7617.

(9185)A

WE are seeking an independent investigator with skills and demonstrated competence in the broad field of cell biology. successful candidate is likely to have had five years post-doctoral experience and should be a Canadian citizen or a landed immigrant. It is expected that the appointee would have a strong research program, develop appropriate collaboration with other faculty, and provide an educational resource to colleagues on the nature of the functioning of eukaryotic cells. It is hoped that this appointment will provide a new dimension in scientific endeavour at McMaster and, at the same time, capitalize on some of the existing strengths within the faculty. Salary, academic rank and departmental affiliation will be negotiated. During the Canadian postal strike, interested candidates are invited to send curriculum vitae and three current letters of reference to: Dr D R McCalla, Faculty of Health Sciences, McMaster University, Dept of Biochemistry, PO Box 1406, Niagara 14302. Otherwise, Falls, NY applications should be sent to: Dr D R McCalla, McMaster University, Dept of Biochemistry, 1200 Main Street West, Hamilton, Ontario L8N (NW778)A

POST DOCTORAL — RESEARCH POSITION

for Biochemist-Cell Biologist available September 1, for two to three years, to identify, isolate and characterize insulin-like growth factor and α-thrombin receptors. (J. Biol. Chem. Vol 256: 2767, 1981) from cultured cells and tissues.

Experience in membrane protein chemistry, monoclonal antibody production, and/or ligand receptor characterization is desirable but not essential. \$15,000 to \$20,000 yearly depending on qualifications.

Send curriculum vitae and names of three references to Dr James F Perdue, Lady Davis Institute for Medical Research — Sir Mortimer B Davis — Jewish General Hospital, 3755 Cote St Catherine Road, Montreal, Que Canada H3T 1E2.

(NW760)A

FACULTY Position - Tenure track Assistant Professorship Eukaryctic Molecular Cell Biologist with interests in some facet of immunclogy. Preference will be given to an individual who has potential for and commitment to developing an independent research program and who has an interest in and an aptitude for teaching graduate, medical and dental students Position available during 1981-82 academic year. Salary commensurate with experience but not less than \$26,000 for a twelve-month appointment. Applicants should submit a letter outlining current and future research interests, curriculum vitae and bibliography and should arrange for three letters of reference to be sent to: Dr Roy Curtiss III, Department of Microbiology, Box 11 SDB, The University of Alabama in Birmingham, Birmingham, Alabama 35294. An Equal Opportunity/ Affirmative Action Employer

(NW776)A

Coláiste na hOllscoile Corcaigh
University College Cork

RESEARCH SCIENTISTS IN MICROBIOLOGY

required to work on the molecular Biology of Nitrogen Fixation in Root Nodule Bacteria

1 Geneticist/Molecular Biologist

preferably with a PhD to work on a project involving the genetic engineering of root nodule bacteria. Capabilities in recombinant DNA technology would be an advantage but is not essential as training will be provided.

2 Microbiologist/Microbial Physiologist

preferably with a PhD degree, to work on the physiology and regulation of CO₂ metabolism in rhizobium. This position is tenable in the first instance for one year with the possibility of renewal for a further year.

These positions are supported by the NBS and available from the 1st October 1981. Salaries will be on the appropriate national scales (IR £6,234 — post-doctoral max, including PRSI) with the point of entry negotiable.

Applications, containing full career details and the names of two referees should be sent as soon as possible to Dr. F. O'Gara, Microbiology Department, University College, Cork, Ireland, from whom further particulars are available.

Coláiste na hOllscoile Corcaigh University College Cork

Ireland

RESEARCH ASSISTANTSHIP GENETICS OF LACTIC STREPTOCOCCI

Applications are invited for a

RESEARCH ASSISTANTSHIP

(supported by the national Board for Science and Technology) to develop a transformation system in the lactic streptococci. Applicants should preferably have a PhD degree and research experience in genetics/microbiology. The appointment is initially for one year from 1st October 1981 and is renewable.

Salary scale:

PhD degree, MSc degree, IRE5,370 — IRE5,798; IRE4,417 — IRE5,073.

Applications with Curriculum Vitae and names and a addresses of two referees should be sent as soon as possible to Dr. C. Daly, Dairy and Food Microbiology Dept., University College, Cork, Ireland.

MIDLAND CENTRE FOR **NEUROSURGERY AND NEUROLOGY**

Electron **Microscopist**

(Basic/Senior Science Graduate)

Applications are invited from experienced graduate Electron Microscopists for this newly established post based in the Pathology Department of this specialist hospital.

The Department, located in new accommodation, is well equipped with several microtomes (LKB, Reichert, Sorvall) and two electron microscopes (Siemens).

The successful applicant will be expected to continue and develop the service, and research elements of the work in CNS. PNS and muscle pathology. He/she will be expected, and encouraged, to initiate and collaborate in research on an aspect of his/her choice.

Whitley Council Conditions of Service applicable, and salary will be in accordance with previous experience/qualifications.

Intending applicants are welcome to visit the laboratory by appointment, please contact Dr M V Salmon, Neuropathologist telephone 021-558 3232 Ext. 314.

Application forms and job descriptions may be obtained by writing to the Hospital Secretary, Midland Centre for Nuerosurgery and Nuerology, Holly Lane, Smethwick, Warley, West Midlands.

Closing date for receipt of applications 28th August 1981.

UNIVERSITY COLLEGE GALWAY **IRELAND**

> **DEPARTMENT OF MICROBIOLOGY**

POSTDOCTORAL RESEARCH **FELLOW**

Applications are invited for the post of Postdoctoral Research Fellow to work on an EEC-supported project on the effects of radiation on the blue-green algae (cyanobacteria). Applications from microbiologists, biochemists, geneticists, etc. should be sent within 2 weeks to: Professor James A. Houghton, Department of Microbiology, University College, Galway, (9193)A Ireland.

FREIE UNIVERSITÄT BERLIN

Klinikum Steglitz IMMUNOLOGY RESEARCH **UNIT WE05**

Position open for MD or PhD with experience in Immunology. Available for 3 years but can be extended. The appointee will have to work on mechanisms of lymphocyte activation and regulation of immune response by activated cells. Salary approximately £10,000 per annum (minus tax), depending on experience, age and family status.

Applications to Professor Diamantstein, Immunology Research Unit, Klinikum Steglitz, Freie Universität Berlin, Hinderburg-damm 30, D 1000 Berlin 45/ (W389)A Germany.

Leeds Area Health Authority (Teaching) **Eastern District** St James's University Hospital

MEDICAL LABORATORY SCIENTIFIC OFFICER

Required to work full time on the regional neonatal hypothyroid screening programme, based in the Department of Chemical Pathology at St James's University Hospital.

Applicants should preferably be State Registered, but other candidates, especially those with degrees in the biological sciences will be considered.

Further details are available from Dr R T Evans, tel. (0532) 33144 ext. 5562, under whose direction the successful candidate will work; or from Dr. R. B. Payne on ext. 5560.

Application forms (to be returned no later than Monday 24th August 1981) available from the Personnel Department, Gledhow Wing, St James's University Hospital, Beckett Street, Leeds LS9 7TF. Tel: (0532) 33144 (9228)A ext. 5103/5851.

MEDICAL RESEARCH COUNCIL CLINICAL AND POPULATION CYTOGENETICS UNIT (MOLECULAR GENETICS SECTION)

AND **MAMMALIAN GENOME UNIT**

POSTDOCTORAL SCIENTIST

Applications are invited for a SHORT-TERM NON-CLINICAL SCIENTIFIC post in this MRC Unit, tenable for 3 years. Candidates of immediately post-doctoral or equivalent status will be preferred.

The appointee will join a group that is using new methods of analysis to map the human genome. Candidates should preferably have a knowledge of genetics, including somatic hybrid cell genetics, and DNA analysis, though this is not essential. Experience of leading a small research group would be an advantage.

Remuneration will be at an appropriate point on the scales for university non-clinical academic staff.

Further information may be obtained from Mr. Alasdair Douglas, MRC Clinical and Population Cytogenetics Unit, Western General Hospital, Crewe Road, Edinburgh EH42XU Tel: 031-332 2471, with whom applications — including a full CV and the names and addresses of two professional referees — should be lodged by Monday, 12th October, 1981.

UNIVERSITY OF LEICESTER DEPARTMENT OF BIOCHEMISTRY RESEARCH ASSISTANT

Applications are invited for the post of research assistant (MRC funded) to work on the relationship between fibronectin, laminin, and collagen and the metastases of human carcinomas. The project will involve protein purification and immunochemical techniques.

Candidates should have a degree (at least 2.ii) in Biochemistry or related disciplines and be available to start as soon as possible.

Preference may be given to candidates with one or more years relevant postgraduate experience. Salary will be on the range £5,285 — £6,880, dependent upon qualifica-

Applications, including CV and the names of two referees, should be sent to Dr DR Critchley, Department of Biochemistry, University of Leicester, University Road, Leicester LE17RH. (9219)A

TUFTS UNIVERSITY SCHOOLS OF MEDICINE

DEPARTMENT OF PHYSIOLOGY Tufts University has instituted a search for

CHAIRPERSON

Department of Physiology. The Department of Physiology is expected to be a center of research and scholarly excellence, as well as providing leadership in physiology instruction for the School of Medicine, School of Dentistry, School of Veterinary Medicine, and the Sackler School of Graduate Medical Science.

Individuals interested in being considered for this position should direct their letters to Dr Seymour Reichlin, Chairman, Physiology Search Committee, Box 275, New England Medical Center Hospital, 171 Harrison Avenue, Boston MA 02111. Tufts has an affirmative action program, and encourages applications from women and members of minority groups.

(NW771)A

UNIVERSITY OF DURHAM DEPARTMENT OF PHYSICS **HEAVY ION FUSION**

Applications are invited for a POSTDOCTORAL SENIOR RESEARCH

ASSISTANTSHIP

tenable for a period of three years from 1st October 1981. The successful candidate will participate in a programme of research devoted to semi-classical calculations of charge transfer processes, making use of the ALCHEMY quantum chemistry package on the Daresbury Laboratory computer. The research is to be directed towards the realisation of fusion by inertial confinement, an integral part of the Energy Programme.

Initial salary in the range £6,070 — £7,700 plus USS.

Applications (3 copies) naming three referees should be sent by 31 August 1981 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars are available. (9211)A

POSTODOCTORAL Fellow to conduct research in the area of peptide synthesis. Selected sequences and analogs of gastrointestinal polypeptide hormones and plasma apolipoproteins are to be synthesized using an automated peptide synthesizer. Synthesized peptides will be used for structure-function studies and for raising and characterizing antibodies used in immunochemical studies. Appointee will be expected to collaborate with research biochemists and physiologists in Divisions of GI and Endocrine surgery and Lipid Research. Substantial postgraduate experience in peptide synthesis is required. Applicants should send curriculum vitae and references to: Dr R F Murphy, Department of Surgery, University of Cincinnati Medical Center, 231 Bethesda Avenue, Cincinnati, Ohio 45267.

(NW774)A

Head of Microbial Biochemistry

Greenford, Middx.

An experienced research scientist is required to manage a multi-disciplinary department of about 40 scientists and technical staff. The major disciplines in the department are biochemistry and microbiology. Research is at present concentrated on the search for selective techniques, often involving target enzymes, aimed at discovering novel biological activity of natural or synthetic origin. Current projects include work with bacteria, fungi and viruses, the design of automated assays and the study of biosynthetic pathways to identify pharmacologically active agents. Planned further development of ecology and fermentation groups will aid the search, in a diversity of habitats, for micro-organisms of possible biological or medicinal application and will optimise the production of any activity of interest.

The successful candidate is likely to be aged 35-45 years and should have a proven innovative research record, together with administrative and communication skills, and the ability to motivate staff to a high standard of scientific achievement.

Major company benefits include a company car, profit sharing bonus scheme, noncontributory pension scheme and relocation assistance if appropriate.

Please write or telephone for an application form, or initially forward a full C.V. to:

The Personnel Manager, Glaxo Group Research Limited, Greenford Road, Greenford, Middlesex. Tel: 01-422 3434, ext. 2568, quoting ref. U/381.

Glax0 Group Research Ltd.

(9227)A

MICROBIOLOGIST

A vacancy has arisen for a graduate microbiologist to work in a small group developing mainly antimicrobial products for use in veterinary medicine.

The work will involve antimicrobial testing of existing and novel compounds, kinetic studies on antimicrobials *in vitro* and *in vivo*, determinative microbiology and field and experimental study support.

A minimum of a good honours degree is essential and preference will be given to candidates (male or female) who can offer relevant experience. Consideration may also be given to candidates with related experience in other fields.

Walton Oaks is pleasantly situated in the Surrey countryside. Conditions of Employment include flexible working hours, a non-contributory pension and life assurance scheme.

For application form (to the returned by 14 August) please telephone Tadworth 4444 Ext. 250 or write to Mrs. D. Pledge, Site Personnel Officer, Beecham Pharmaceuticals Research Division, Walton Oaks, Dorking Road, Tadworth, Surrey. (9186)A

MOLECULAR GENETICS Ph.D's

THE INTERNATIONAL PLANT RE-SEARCH INSTITUTE (IPRI) invites applicants for its rapidly expanding programs in advanced molecular genetics. Applicants with significant records of frontier achievements are invited to join a strong team of innovative scientific leaders in the pleasant San Francisco area.

Send résumé with recent publications to:

DIVISION OF MOLECULAR GENETICS, IPRI, 853 Industrial Road, San Carlos, Calif. 94070.

Equal Opportunity Employer, M/F

(NW780)A

WHY NOT JOIN US AT THE FRONTIER OF TOXICOLOGICAL RESEARCH!

The Food and Drug Administration's National Center for Toxicological Research located in Jefferson, Arkansas has two exciting and challenging positions available. Both positions are in the Senior Executive Service with maximum salaries of \$50,112.

One position, the Associate Director for Research, involves serving as key advisor to the Center Director and directing a multidisciplinary scientific and professional staff engaged in research programs in the areas of chemistry, carcinogenesis, mutagenesis, teratogenesis, microbiology, immunology and biometry. The other position, the Associate Director for Chemical Evaluation, also involves serving as key advisor to the Center Director but requires the direction of a multidisciplinary scientific and professional staff engaged in coordinating the comprehensive toxicological evaluation of chemicals and related activities in the areas of pathology, nutrition and diet preparation, and animal husbandry.

Both positions need individuals who have professional experience in directing broad scientific programs; ability to deal effectively with high level governmental officials, the scientific/academic communities, national/international medical and health-related organizations and others; and the ability to implement equal employment opportunity programs. Applicants should have a doctorate in chemistry, biochemistry, physiology or related biological sciences and an international reputation in toxicology, chemistry, comparative metabolism, biochemistry, molecular biology, or related biological/toxicological fields.

If you feel you are qualified send a curriculum vitae to Jim Keady, Division of Personnel Management (HFA-440), Food and Drug Administration, Parklawn Building, Room 9-90, 5600 Fishers Lane, Rockville, Maryland 20857. If you need more information call Mr. Keady collect, on 301-443 3634.

These positions can also be filled by current commissioned officers of the US Public Health Service, or by former officers willing to rejoin the Corps.

An Equal Opportunity Employer.

(NW785)A

INSTITUTE OF CHILD HEALTH University of London POST DOCTORAL RESEARCH SCIENTIST

required for three year project (commencing October 1981 or as soon as possible thereafter) to investigate the immunological factors controlling tolerance to food antigens and their disturbance in diseases caused by food allergy. Initial salary within the range £7,442 — £8,257 pa (inc. London Weighting) on scale 1A for Research and Analogous Staff.

Further information: Dr R J Levinsky or Dr M W Turner, Department of Immunology, Institute of Child Health, 30 Guilford Street, London WC1N 1EH. Tel 01-242 9789 Ext. 133/30/N. (9225)A

UNIVERSITY OF LIVERPOOL CENTRE FOR

BIOMATERIALS RESEARCH

Applications are invited for the post of Senior Research Assistant in the Centre for Biomaterials Research. Candidates should hold or expect to receive their PhD. Work concerns the interaction between tissue and implanted Carbonaceous material.

Initial salary within the range £6,070 — £6,880 per annum.

Application forms and further particulars may be obtained from The Registrar, The University, PO Box 147, Liverpool L69 3BX, by whom completed forms should be received not later than 28th August, 1981. Quote Ref. RV/856.

(9202)A

EUROPEAN MOLECULAR BIOLOGY LABORATORY

Applications are invited for a position at the European Molecular Biology Laboratory Outstation on the Deutsches Elektronensynchrotron (DESY) site at Hamburg as

HEAD OF OUTSTATION

The EMBL Outstation has been established to facilitate the use for biological research of the very high-intensity X-ray beams that emerge from the synchrotron and its storage ring DORIS. The Outstation, whose activities the Head will direct, has a staff of 15 and two functions, namely to provide services to visiting biologists wishing to use cynchrotron radiation and to carry out research in some important field of molecular biology to which techniques using high-intensity X-ray beams can make major contributions.

Applicants should be molecular biologists who have extensive experience of, and have made substantial contributions to, research in biological applications of diffraction or scattering methods, or other X-ray techniques. Experience of synchrotron radiation research and the design and construction of physical instruments will be an advantage. Applicants should have experience of leading research teams and of the administration and managerial problems involved. Knowledge of German will be helpful.

The salary offered to the successful candidate will be between DM 6000 and DM 7500 monthly, after deduction of tax, in addition to which certain allowances are payable, depending on personal circumstances.

Please write for an application form, quoting reference no. 81/13, to: The Director General, EMBL, Postfach 10.2209, D — 6900 Heidelberg, Germany. (W391)A

KING'S COLLEGE LONDON DEPARTMENT OF BIOPHYSICS POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a post-doctoral research assistantship to study the regulation of globin gene expression during the development of the frog, *Xenopus laevis*. Expertise in Molecular biology and a knowledge of vertebrate development would be beneficial. Post tenable for up to 3 years from 1 October 1981. Salary in the range £6,475 — £7,700 pa plus £967 London allowance. USS.

Apply in writing as soon as possible with a curriculum vitae and the names and addresses of two referees, to Dr R K Patient, Imperial Cancer Research Fund, Mill Hill, London NW7 1AD. (9205)A

PHYSICIST OR PHYSICAL CHEMIST

for developments of sensitive, optical methods for trace gas measurements in the atmosphere.

Permanent position possible. Annual salary, depending on age or qualifications, in the range of 45,000 - 55,000 DM.

Curriculum vitae, summary of research interests, publication list and at least 3 references or letters of recommendations to be sent to Dr Paul Crutzen, Max-Planck-Institut fuer Chemie, Postfach 3060, D-6500 Mains/West-Germany before September 12, 1981. (W390)A

THE ROWETT RESEARCH INSTITUTE

Bucksburn, Aberdeen AB2 9SB

RESEARCH WORKER TO STUDY RED DEER

Applications for an appointment in the Applied Nutrition Department of the Institute are invited. The work will be concerned with the elucidation of the nutrient requirement of red deer kept under lowland farm conditions and their ability to meet these requirements from grazed pasture, or from conserved and other feeds.

Applicants should hold a First or Upper Second Class Honours degree in Agriculture or a Biological Science. Previous experience of nutritional research, particularly with farm livestock or related to pasture utilisation, would be an advantage.

The appointment will be as Scientific Officer (salary £4,809 to £6,480 per annum) or Higher Scientific Officer (£6,075 to £7,999 per annum), grade and starting salary depends on experience. At least two years' relevant post graduate experience is required for Higher Scientific Officer grading.

There is a non-contributory pension scheme.

Further details of the post may be obtained from the Secretary of the Institute, to whom applications should be submitted together with the names and addresses of two referees. Closing date 31 August 1981.

(9233)A

MEDICAL RESEARCH COUNCIL

Virology Unit Institute of Virology University of Glasgow

CAREER (TENURE) OR SHORT TERM (3-5 YEARS) APPOINTMENT **VIRUS**

GENETICIST/MOLECULAR **GENETICIST**

Applications are invited for this Non-Clinical Scientific post which may be filled by either an MRC Career appointment (tenure to normal retiring age) or a Short-Term appointment of three (to five) years according to the age and experience of the successful candidate. A career appointment will be tenable at the MRC Virology Unit in the first

The Institute of Virology is seeking a senior scientist or alternatively a post-doctoral scientist with experience in Molecular Genetics, preferably (but not exclusively) with interests in herpesvirus and/or virusspecified enzymes. The appointment provides a unique opportunity to participate in a comprehensive and multi-disciplinary research programme centred on the Genetics and Molecular Biology of Herpesviruses. The Institute provides excellent facilities and technical support for all types of biological, biochemical and recombinant DNA research. The successful applicant will be expected to collaborate with other members of the Institute whilst pursuing a vigorous and independent research programme within the general framework of research on erpesviruses as agreed with the Director.

Remuneration will be at an appropriate point on the scales for University non-clinical Academic staff. Applicants should send a Curriculum Vitae giving full details of qualifications and experience and names and addresses of three professional referees, to the MRC Unit Director, Professor J H Subak-Sharpe, Institute of Virology, University of Glasgow, Church Street, Glasgow G11 5JR. Applications should be received by Friday, 11th September, 1981. (9240)A

KING'S COLLEGE LONDON (University of London) DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a

POST-DOCTORAL RESEARCH ASSISTANT

financed by the Medical Research Council and tenable for up to 3 years commencing on 1st October, 1981 or as soon as possible thereafter.

The starting salary will be £6,070 plus £967 London Allowance.

Research work will involve studies on Structure, Function and Biogenesis of Ribosomes from Yeast Mutants and Mechanisms of Antibiotic Resistance.

Applications including a full curriculum vitae and the names and addresses of 3 referees to Dr Michael Cannon, Department of Bio-chemistry, King's College London, Strand, London WC2R 2LS by 17th (9184)AAugust, 1981.

ENTOMOLOGIST

For National Collection of Insects

The British Museum (Natural History) is primarily an institution for taxonomic research and the Department of Entomology contains the largest and most comprehensive collection of insects in the world.

The successful candidate will carry out taxonomic research. particularly on parasitic wasps of the family Ichneumonidae and will be concerned with the improvement of the National Collection of Insects through collecting, rearing and exchange. The work includes curatorial and supervisory duties.

Candidates should have a 1st or 2nd degree, preferably specialising in Entomology at least 2 years postgraduate experience, including experience of current trends in systematics, such as mathematical and phylogenetic approaches, plus field experience.

> Appointment as Senior Scientific Officer £8,660 -£10,635 or Higher Scientific Officer £7,090 - £9,015. Level of appointment according to qualifications and experience. Salaries under review.

For futher details and application form (to be returned by 21 August 1981) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please quote ref: SB/70/DK.

(9223)A

British Museum (Natural History)

UNIVERSITY OF THE WITWATERSRAND Johannesburg

DEPARTMENT OF GEOLOGY

LECTURER/SENIOR LECTURER IN STRUCTURAL GEOLOGY

Applications are invited from suitably qualified persons, regardless of sex, race, colour or national origin, for the above post in the field of structural geology. Applicants should have a PhD degree and be fully conversant with modern developments in structural geology, and methods of structural analysis and their application. Although not a prerequisite for appointment, an interest in the application of these techniques to mineralised terranes would be an advantage in view of the Department's interest in mineralisation in Archaean terranes and other mineralised provinces.

The starting salary will be determined according to quali-fications and experience within the following ranges: Lecturer: R10,995

— R19,230 pa. Senior Lecturer:
R14,370 — R20,850 pa.

Further details relating to this post and the attractive fringe benefits are included in an information sheet obtainable from the London Representative, University of the Witwatersrand, Chichester House, 278 High Holborn, London WClV 7HE, or from the Registrar (Staffing), University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa 2001, with whom applications, including the names of three referees, should be lodged not later than 1st September 1981. (9214)A

The Royal Marsden Hospital, Fulham Road, London SW3

Cytogeneticist

required immediately to work at the above postgraduate teaching hospital on a research project designed to study the relationships between chromosomes and prognosis in acute leukaemia. The post is funded by a grant from the Medical Research Council, and is for a period of three years. The salary is on the Basic Biochemical grade scale: £5,366 to £7,637 p.a. according to qualifications and experience.

Application form from the Personnel Officer — Tel: 01-352 8171 Ext: 446.

Closing date 20th August 1981.

CHURCHILL HOSPITAL **DEPARTMENT OF MEDICAL GENETICS** SCIENTIFIC OFFICER

required in the Cytogenetics Laboratory, which provides a full range of cytogenetic and cell culture techniques, and is responsible for all diagnostic cytogenetics in the Oxford Region. Training could be given to a suitably qualified but inexperienced applicant.

Applications, including the names and addresses of two referees, should be sent to Dr. Dick Lindenbaum, Department of Medical Genetics, Old Road, Headington, Oxford OX3 7LE, within two weeks of the publication of this advertisement.

Yale University

DIRECTOR

PEABODY MUSEUM OF NATURAL HISTORY

Applications are invited for the position of Director of the Museum at the rank of full professor, and with appointment (according to field) to the Departments of Biology, Geology and Geophysics or Anthropology. Yale University is seeking a scholar of international reputation who will develop interdisciplinary research and teaching programs in the natural sciences through the Peabody Museum and the affiliated academic departments.

Applications, including a curriculum vitae and the names of three references, should be sent to Professor Keith S. Thomson, Dean of the Graduate School of Arts and Sciences, Yale University, P.O. Box 1504A, Yale Station, New Haven CT 06520. Closing dates for applications — September 30, 1981.

Yale University is an equal opportunity, affirmative action employer.

(NW773)A

Research Institute Director

The University of Nebraska Medical Center invites nominations and applications for the position of Director, Eppley Institute for Research in Cancer and Allied Diseases. The Institute is federally funded for research in chemical and environmental carcinogenesis.

Recently new research support has been provided by the state. Qualifications include an earned doctorate, outstanding research accomplishments, and administrative skills, Responsibilities include administration and leadership of the Institute in developing and administering research programs.

Applications and nominations, accompanied by a curriculum vitae and the names of three references, should be received by October 1, 1981. Direct communications to: Dr. David T. Purtilo, Chairman of the Search Committee, University of Nebraska Medical Center, 5001 Wittson Hall, 42nd and Dewey Avenue, Omaha, Nebraska 68105.

THE UNIVERSITY OF NEBRASKA
IS AN AFFIRMATIVE ACTION/EQUAL
OPPORTUNITY EMPLOYER

(NW779)A

LA TROBE UNIVERSITY Melbourne, Australia

SCHOOL OF BIOLOGICAL SCIENCE DEPARTMENT OF GENETICS AND HUMAN VARIATION

LECTURER IN GENETICS (FIXED TERM)

A position is available for a lecturer with research experience in eukaryote gene structure and expression, possibly with an interest in development. Applicants should have a strong training in general genetics, and teaching in prokaryote genetics will be required.

The appointee will be actively involved in research, including the supervision of honours and postgraduate students. The facilities of the Department include glasshouses, growth cabinets, constant temperature rooms, a Cl containment room, analytical and other centrifuges, and routine items of potential assistance for a molecular geneticist.

Although negotiable, it is hoped that the appointee will commence duties early in 1982.

This position is for a fixed term of four years. The University reserves the right not to make an appointment to the position.

Salary: \$A19,132 — \$A25,132.

Further information and application forms are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close on 9th August 1981. (9183)A

SOUTH AFRICAN INSTITUTE FOR MEDICAL RESEARCH

SERUM & VACCINE DEPARTMENT DEPUTY HEAD

Applications are invited from suitably qualified Medical or Science graduates for the above post in our laboratories situated on the outskirts of Johannesburg.

The incumbent will be responsible to the Head for the day to day running of the Serum and Vaccine Production units and must assume responsibility for the running of the department in the absence of the Head.

Duties will, inter alia, include supervision of the administration of the department, which includes aerobic and anaerobic vaccine production units, a serum production unit, dispensing, blending and bottling unit, labelling and an animal house for small laboratory animals, research and development of new vaccines and equine antigens and the improvement of existing processes.

In addition to a competitive salary, the following fringe benefits apply, namely, staff pension fund, subsidised medium aid scheme, annual service bonus (13th cheque), 30 days' annual leave and housing bond allowance, where applicable.

A member of the Institute staff will interview applicants in London in the latter part of September or early October. All applications, including detailed curriculum vitae should reach the undermentioned by 31 August 1981, in order that an interview may be arranged.

Head: Personnel Services, SAIMR, PO Box 1038, Johannesburg, Republic of South Africa. Telephone: 011-725 0511 (W388)A

UNIVERSITY OF LONDON British Postgraduate Medical Federation

CARDIOTHORACIC INSTITUTE CARDIAC MUSCLE RESEARCH UNIT

PHYSIOLOGIST — POST-DOCTORAL

A vacancy exists for a post-doctoral physiologist to work on a project utilising intracellular ion-selective microelectrodes in cardiac muscle. Previous experience in electrophysiology would be an advantage. The appointee will work in a multidisciplinary team with extensive and varied research interests relating to the heart.

Salary on appropriate point of postdoctoral Research Assistant scale 1A, currently £6,070 — £10,575 + £967 London Weighting Allowance. The post is superannuable in the Universities' Superannuation Scheme

Further details can be obtained from Dr Poole-Wilson (01-486 3043). Applications with full curriculum vitae, list of publications and names and addresses of three referees, to the Secretary, Cardiothoracic Institute, 2 Beaumont Street, London W1N 2DX. Closing date 28th August 1981. (9216)A

AGRICULTURAL RESEARCH COUNCIL A VETERINARIAN

Is required at I.R.A.D. to join a team investigating the role of virus and bacterial pathogens in the aetiology of outbreaks of diarrhoea in calves and piglets.

Candidates must be members of the Royal College of Veterinary Surgeons; some bacteriological experience is essential and a higher degree would be an advantage. Experience in organising programmes of disease investigation on farms would be useful.

The person appointed will be encouraged to collaborate with a team working on genetic and acquired resistance to E. coli enfections.

Salary scale: Veterinary Research Officer £7,999 — £12,540 p.a. depending on age and experience (under review). Noncontributory pension scheme.

Application forms from: Secretary, Institute for Research on Animal Diseases, Compton, Nr. Newbury, Berks RG16 0NN quoting ref: 466. Closing date: 15/8/81. (9212)A

In the Faculty of Technical and Natural Sciences (Technisch-Naturwissenschaftliche Fakultät) of the Johannes Kepler University, Linz, Austria, the position of a full PROFESSOR IN BIOPHYSICS

is vacant

The candidate for this post will be expected to devote his research activites to experimental membrane biophysics as his main effort. His teaching should be focussed on which enable graduate courses, which enable graduate students in physics, chemistry, computer sciences and mathematics to acquire knowledge in biophysics. Applicants should be proficient in German.

Applications including a curriculum and a list of publications should be sent before October 30th, 1981, to the Dean (Dekan) of the Faculty, Altenbergerstr. 69, A-4040 Linz, Austria. Dean Prof Dr Bruno (W394)A Buchberger.

RESEARCH TECHNICIAN (Grade 3)

Applications are invited from suitably qualified persons interested in working on DNA gyrase and the enzymology of DNA supercoiling in bacteria and eukaryotes. Experience in the techniques of DNA bio-chemistry, protein chemistry or enzymology an advantage. This post, funded by the Cancer Research Campaign, commences on or around 12 October and is renewable annually for up to three years. Salary in the range £4,672 — £5,473 plus £1,027 London Allowance. 37½ hour week, Monday to Friday. Five weeks annual holiday. Superannuation

Apply in writing by September 7 1981, with a curriculum vitae and the names and addresses of two referees, to Dr L M Fisher, Laboratory of Molecular Biology, Building 2, Room 322, National Institutes of Health, Bethesda, Maryland, USA 20205. (NW783)A

UNIVERSITY OF ABERDEEN POST-DOCTORAL RESEARCH FELLOW (supported by

The British Heart Foundation)

Applications are invited for the above post, tenable for a maximum of three years, from protein biochemists to work on the structure of fibrin and fibrinogen in human atherosclerotic plaques, one aspect of a long-term research programme on atherosclerosis for which the Research Fellow will take major responsibility. Experience in modern methods of protein separation essential.

Salary on range 1A scale, starting point up to a maximum of £6,985 per annum, with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 21 August 1981. (9210)A

INSTITUTE OF CHILD HEALTH University of London **ELECTRON MICROSCOPY** SCIENTIFIC OFFICER

required to work with a group investigating pulmonary vascular disease in children. Applicants should have experience in fixation of human tissue and preparation and staining of ultrathin sections for examination in a Transmission Electron Microscope. Some knowledge of immunolabelling techniques for light and electron microscopy would be an advantage.

Whitley Salary Scales for Medical Laboratory Scientific Officers, according to age, qualifications and experience.

Application forms may be obtained from Miss Janet Keeble, Administrative Assistant (203906), Institute of Child Health, 30 Guilford Street, London WC1N2EH (telephone 01-242 9789) N.

(9224)A

CSIRO

AUSTRALIA

Research Scientist (Research Fellow)

Division of Mineral Chemistry Port Melbourne, Victoria

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,400 employees - 2,500 of whom are research and professional scientists located in Divisions and Sections throughout Australia

Field: Hydrometallurgical Treatment of Gold Ores. General: The Division conducts research in the fields of extractive metallurgy, electrochemistry, surface chemistry, and solid-

state chemistry. With the objective of developing improved methods of treating Australian gold ores, the Division is undertaking a research project on novel leaching methods for recovery of gold and

Duties: To conduct investigations into novel gold and silver recovery processes. In particular, to study the chemical and mineralogical factors which effect the dissolution rate and extraction of these metals from ores.

Qualifications: PhD or equivalent in an appropriate branch of chemistry, chemical metallurgy, or chemical engineering

Salary: Research Scientist (Research Fellow) \$A19,662 -\$A24,100 p.a.

Tenure: Two years initially. Superannuation benefits available. Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting reference number M9563 should reach: The Personnel Officer, Australian Scientific Liaison Office, Australia House, Strand, London WC2B 4LA by 28 August 1981. Applications in USA and Canada should be sent to: The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue NW, Washington DC 20036.

Current vacancies in CSIRO appear on PRESTEL page 252903.

Molecular Biologists

Enzo Biochem, Inc. of New York is seeking qualified scientists to join its research program in recombinant DNA. We are interested in persons who have at least two years of specific recombinant DNA research. The growth of Enzo's activities in this area have created the need for several Ph.D. level scientists.

The recombinant DNA division is cloning and sequencing genes both from mRNA and from genomic DNA. We are also developing new cell and vector systems designed to improve the level of expression of cloned genes in several bacterial species as well as in yeast and plants.

Our new research facilities are located in New York's Soho district. This is a pleasant and superbly "urban" neighborhood. We are an equal opportunity employer M/F.

Persons interested should send a copy of their

Personnel Department, Enzo Biochem, Inc. 325 Hudson Street, New York, New York 10013

AGRICULTURAL ZOOLOGIST SENIOR/HIGHER/SCIENTIFIC OFFICER £4,809 — £9,619 (under review)

Age limit: Applicants must not be more than 55 years of age on the closing date (ie born on or after 20th August 1926)

Closing date: 20 August 1981 Job Ref. SB 81/81/NN

Tel. ext 256

DEPARTMENT OF AGRICULTURE (NORTHERN IRELAND) AGRICULTURAL ENTOMOLOGY RESEARCH DIVISION

The appointment will be at Senior Scientific Officer, Higher Scientific Officer or Scientific Officer level.

The successful applicant will be expected to conduct both basic and applied research in the field of Agricultural Entomology and/or Plant Nematology and may also be responsible for the provision of specialist advice.

Experience in the use of electrophoretic techniques is desirable but not essential.

The successful applicant may also be required to undertake teaching duties in the Faculty of Agriculture and Food Science, The Queens University of Belfast.

Senior Scientific Officer

Applicants must possess a first or second class honours degree in Zoology, Agricultural Zoology or a related subject and at least 4 years' appropriate post graduate experience in a relevant field.

Higher Scientific Officer

Applicants must possess an honours degree as above and at least 2 years' appropriate post graduate experience in a relevant field.

Scientific Officer

Applicants must possess an honours degree as above.

The Civil Service Commissioners may decide to interview only those applicants who appear from the information available, including level of academic attainment and relevant experience to be best qualified.

Salary Scales (under review) Senior Scientific Officer

£7,644 — £9,619 £6,075 — £7,999 £4,809 — £6,480

Higher Scientific Officer
Scientific Officer
Scientific Officer

In addition there is a non-contributory pension scheme apart from a 1 % % deduction from salary to cover widow's benefits in the case of male officers.

Grading and starting salary will be related to qualifications and experience.

The post is open to both men and women. Please write or telephone for an application form (using the extension number indicated and quoting the job reference) to the Civil Service Commission, Rosepark House, Upper Newtownards Road, Belfast BT4 3NR (telephone Dundonald 4585). Completed forms must be returned to arrive not later than the closing date stated. (9187)A

NORTHERN IRELAND CIVIL SERVICE

NATIONAL BIOLOGICAL STANDARDS BOARD DEPARTMENT OF VIRAL PRODUCTS

POST DOCTORAL SCIENTIST

An opportunity has arisen for a research scientist to join a group working at the Institute on the genetic structure of polioviruses with particular reference to studies of poliovaccines used in man.

The appointment is of a three year duration only and is suitable for a candidate who has recently completed a PhD degree in a relevant field. The successful candidate should have experience in virology and/or nucleic acid biochemistry.

The salary payable is in accordance with qualifications age and experience on scale £7,037 - £10,717 p.a. inclusive.

Application forms and further details from Personnel Officer, N.I.B.S.C., Holly Hill, Hampstead, London NW3 6RB. Telephone 01-435 2232, quoting reference n.o. SG 293. Closing date 28 August 1981. (Informal enquiries please contact Dr. G. Schild).

THE UNIVERSITY OF LEEDS DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a post of POSTDOCTORAL RESEARCH FELLOW

and a post of PREDOCTORAL

RESEARCH ASSISTANT in the above Department for work on an MRC funded project on molecular organisation and expression of androgen-responsive genes.

Candidates for the post of Research Fellow should have, or shortly expect to have a PhD, together with experience in Molecular Biology, Recombinant DNA Technology or related areas. For the post of Research Assistant, a good honours degree in Biochemistry, Genetics, Microbiology or a related subject is required and laboratory experience would be an advantage.

Both posts available from 1 October 1981 for a fixed period of up to three years. Salary on the IA Scale for Research and Analogous Staff (Research Fellow) (£6,070 — £10,575), or the IB Scale (Research Assistant) (£5,285 — £7,700), according to age, qualifications and experience.

Informal enquiries may be made to Dr S J Higgins. Telephone Leeds 31751 ext. 7439.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 83/37/D. Closing date for applications 28th August 1981.

(9204)A

THE ROWETT RESEARCH INSTITUTE Bucksburn, Aberdeen AB2 9SB

DEPARTMENT OF MICROBIAL BIOCHEMISTRY

POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited for a post-doctoral research assistantship to join a team undertaking research on the enzymatic conversion of the carbohydrates of straw into soluble sugars. Initially the work will be concerned with the isolation of mutant strains of fungi with improved capacities for producing polysaccharide-hydrolysing enzymes.

The project is funded in part by the Commission of the European Communities and this appointment will be for a period of two years in the first instance, with probable extension to three years. The post will be supported by non-graduate assistants.

Candidates should have a good Honours degree and a PhD degree and relevant experience in microbiology, preferably including isolation of mutants.

Starting salary, depending on qualifications and experience, will be in the range £6,075 to £6,683 per annum (scale currently under review). Superannuation Scheme.

Applications, including curriculum vitae and the names of two referees, should be sent to the Secretary of the Institute, as soon as possible.

(9234)A

SENIOR PROFESSORSHIP IN INORGANIC CHEMISTRY

Professor, University of Florida, inorganic chemistry, with an active program in internationally recognized inorganic chemical research. Teaching duties may include undergraduate and graduate level inorganic courses. Top-level salary with major departmental research support.

Preferred starting date: August, 1982. Direct inquiries or applications to Professor Harry H Sisler, Chairperson of Search Committee, Department of Chemistry, University of Florida, Gainesville, FL 32611.

Applications should include complete curriculum vitae, bibliographies of publications, indication of on-going and probable future research interests, and a list of three or more references who will be asked to supply letters of recommendatin (a university personnel requirement). The University of Florida is an Affirmative Action/Equal Employment Opportunity Employer. Application deadline: November 15, 1981. (NW766)A

TUMOR IMMUNOLOGY

PRE/POSTDOCTORAL

position available immediately. Monoclonal Ab, characterization for human tumor Ag.

Send CV, three ref to; Dr Daniel Eskinazi, USC, PO Box 77912, GER 323, Los Angeles, CA 90007 EOE/MFH (NW765)A

UNIVERSITY OF THE WITWATERSRAND

Johannesburg and

SOUTH AFRICAN INSTITUTE FOR MEDICAL RESEARCH CHAIR OF CLINICAL BIOCHEMISTRY

Applications are invited for appointment to the above post on the joint staff of the University and the Institute in the School of Pathology. Although preference will be given to medically qualified persons, applicants with a non-medical background will also be considered.

The salary attached to the post is R29 190 per annum and in certain circumstances there is provision for generous remuneration for approved overtime duties.

The appointment will be made on University conditions of service but provision exists for the successful applicant (if already a member of the Institute staff) to elect to remain on Institute conditions.

Intending applicants should obtain the information sheet relating to this post from the London Representative, University of the Witwatersrand, Chichester House, 278 High Holborn, London WC1V 7HE, or from the Registrar (Staffing), University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa 2001, with whom applications should be lodged not later than 31 August 1981. (9213)A

ASSOCIATE PROFESSORSHIP (C3) WITH TENURE AVAILABLE AT THE INSTITUTE OF NEUROBIOLOGY DEPARTMENT OF BIOLOGY UNIVERSITY OF HEIDELBERG (EOAAE)

Candidates should be experienced in developmental and/or cell biological research and interested in genetic, biochemical and/or cellphysiological studies of higher nervous systems.

The position includes participation in teaching biology.

Send (until October 15, 1981) application including curriculum vitae and publication list to: Dr. Melitta Schachner, Institut Fuer Neurobiologie, Im Neuenheimer Feld 504, 6900 Heidelberg, Fed. Rep. Germany. (W393)A

THE UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF PHYSIOLOGY FACULTY OF MEDICINE AND DENTISTRY

Applications are invited for the post of Research Fellow 1A to work on the role of phospholipases in the control of membrane properties of skeletal muscle. Applicants should have experience in membrane biochemistry or enzymology.

Salary £6,070 — £10,575 with superannuation. Maximum starting salary £6,880. Post supported by the Wellcome Trust for three years.

Further information from Dr ME Smith, Physiology, 021-472 1301 ext. 244.

Applications (three copies) to Assistant Registrar, Medical School, Birmingham B15 2TJ by 22nd August 1981. Quote Ref. RF/Phys/ 581. (9222)A

UNIVERSITY OF OTAGO Dunedin, New Zealand LECTURER IN PHYSICS

Applications are invited for the position of Lecturer in the Department of Physics. The Department has recently accepted responsibility for teaching some of the courses in Computer Science (most of which are taught by the Computing Centre staff) and will shortly increase teaching of electronics and microelectronics at postgraduate level. Consequently preference will be given to candidates with strengths and experience in these areas.

The appointee will be expected to pursue research in one of the fields currently pursued in the Department (atomic and laser physics, radio and space physics, environmental and applied physics), or in electronics. The Department has recently occupied a well-appointed, modern building and has several mini and microcomputers for teaching and

Salary: NZ\$19,140 — NZ\$23,520 per annum.

Further particulars are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF, or from the Registrar, PO Box 56, Dunedin, New Zealand.

Applications close on 30 September 1981. (9217)A

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

PHYSICAL SCIENCES DEPARTMENT A GRADUATE

is required to work for 18 months on the effect of heat on the proteins and enzymes of human milk. The work involves a study of the kinetics of their heat denaturation to improve knowledge of the effects of pasteurisation treatments on human milk.

Qualifications: First or Upper Second Class Honours degree in biochemistry or food science.

Appointment, for a limited period of only 18 months, will be as Scientific Officer; current salary scale £4,809 to £6,480.

Application forms are obtainable from the Secretary, NIRD, Shinfield Reading RG2 9AT. Quote reference 81/22

Closing date: 14 August 1981 (9162)A

Royal Postgraduate Medical School

(University of London) CLINICAL PHARMACOLOGY TECHNICIAN

required to join a group investigating cell surface receptors that regulate mast cell degranulation. Duties will include measurement of mediator release, adenylate cyclase activation, methylation of membrane lipids, and quantitation of surface receptors by radio-ligand binding. Applicants should have a degree or HNC in biochemistry or an appropriate subject. Experience in the following an advantage: handling of radiolabelled compounds, receptor pharmacology, cell culture, immunology, but training will be given. The post is funded by the Wellcome Trust for 3 years with possible renewal for a further 2 years. Salary on the scale £5,427 — £5,914 inclusive of London

£5,914 inclusive of London Allowance a year (under review).

Application forms and further details are available from the Personnel Office, Royal Postgraduate Medical School, 150 Du Cane Road, London W12 0HS quoting reference number 20/305.

ALBERTA HERITAGE MEDICAL FOUNDATION RESEARCH POSITIONS IN ENDOCRINOLOGY

The Endocrine Research Group at The University of Calgary, Faculty of Medicine, Calgary, Canada, will be seeking up to four new faculty members over the next two years. Although junior faculty positions are envisioned, applications from more senior investigators will be considered. Preference will be given to those interested in molecular or clinical endocrinology with expertise in recombinant DNA technology, peptide synthesis and/or microsequencing, membrane chemistry or in the study of hormone action in tissue culture systems.

Enquiries, including a complete curriculum vitae and at least two personal references, should be directed to:

Dr. Y. Lefebvre, Head Endocrine Research Group, Faculty of Medicine Health Sciences Centre 2961 The University of Calgary 3330 Hospital Drive N.W. Calgary, Alberta T2N 4N1

(NW786)A

PROFESSORSHIP in the Clinical Smell and Taste Research Center at the University of Pennsylvania. Established scientist working in olfactory neurophysiology in Physiology and/or Otorhinolaryngology Department. Based in VA Hospital. Preferably with an MD degree. Write to Dr James B Snow, Jr, Department of Otorhinolaryngology and Human Communication, 5th Floor Silverstein, Hospital of the University of Pennsylvania, Philadelphia, Pennsylvania 19104 and provide three letters of reference. The University of Pennsylvania is an Equal Opportunity/ Affirmative Action Employer.

(NW751)A

UNIVERSITY of Leeds Rheumatism Research Unit. Laboratory Research Technician Grade 3 required for Clinical Pharmacology Unit, Royal Bath Hospital, Harrogate, North Yorkshire. The work will include biochemical and drug assays in biological fluids. Applicants must have at least ONC or equivalent qualification, and previous laboratory experience. The appointment will be for 2 vears initially from 1st October 1981. Salary scale £4,672 £5,473. Applications giving details of age, education and experience to Dr ME Pickup at the Harrogate address. (9198)A

TEMPORARY LECTURER GRADE II IN MICROBIOLOGY

(£6,462 — £10,431)

Applications are invited for a Temporary appointment starting on 1 September 1981 (or as soon as possible after that date), for two academic terms ending on 30 April 1982. Applicants should have a first degree and post graduate experience in Microbiology or a closely related subject.

Further details and form of application from the Assistant Director (Administration) Trent Polytechnic, Burton Street, Nottingham NG1 4BU. Closing date 10 August 1981.

TRENT POLYTECHNIC NOTTINGHAM

TRANSGENE

STRASBOURG - FRANCE

TRANSGENE was launched by leading industrial and financial French groups.

TRANSGENE carries out high level research oriented towards applications of medical and industrial importance.

TRANSGENE is now expanding its laboratory and invites applications from:

MOLECULAR GENETICISTS

EXPERTS IN RECOMBINANT DNA TECHNIQUES AND CHEMICAL SYNTHESIS OF DNA

IMMUNOLOGISTS

from the post doctoral level to group leaders to join its first team of highly qualified scientists

Expertise in the use of Bacillus subtilis, Yeast and Eucaryotic cells as cloning systems is of special interest.

Salaries will be competitive and commensurate with qualification.

Knowledge of French is not necessary.

STRASBOURG is a pleasant historical town, located in the heart of Europe, very close to GERMANY and SWITZERLAND.

The laboratory is located on the University campus and enjoys close contacts with well known groups in fundamental research.

For confidential consideration, send a CV, a list of publications and indication of salary requirements to:

> TRANSGENE S.A. attn J-P LECOCQ B.P. 146 67028 STRASBOURG CEDEX

(W392)A

MONASH UNIVERSITY Melbourne, Australia DEPARTMENT OF BIOCHEMISTRY **FIXED TERM (3 YEAR) LECTURER**

Applicants with PhD invited to undertake teaching duties to science and medical students, and participate in the ongoing research programme into the biogenesis of mitochondria. Candidates should have a general background in biochemistry with research experience in technique of molecular biology such as DNA cloning and sequencing.

Applicants with experience in yeast studies preferred, but this is not essential. Enquiries to Professor A W Linnane FRS, FAA in the University. Salary: \$A19,821 — \$A26,036 pa.

Applications including Ref no 30212, curriculum vitae and 3 referees to the Registrar, Monash University, Clayton, Victoria 3168, Australia with copy to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF by 14/8/81. Conditions of appointment the can be obtained from (9201)A Association.

GEOPHYSICIST

Faculty position for 12-month, tenure-track appointment. A seagoing marine seismologist with interests in seismic reflection, refraction or microseismicity is sought. Candidates with strong backgrounds in non-marine seismology or other branches of marine geophysics will also be considered. Duties include maintaining active research programs and obtaining outside funding, teaching graduate courses and supervising graduate students. Rank is Associate Professor.

Applicants who meet all requirements, but have less required for Associate Professor rank, will be considered for appointment at the rank of Assistant Professor. Salary \$24,000 to \$37,000, commensurate with experience.

Send résumé and names of three references by 1 October 1981 to G Ross Heath, Dean, School of Oceanography, Oregon State University, Corvallis, Oregon, 97331. OSU is an Affirmative Action/ Equal Opportunity Employer

(NW789)A

LOTHIAN REGIONAL COUNCIL NAPIER COLLEGE OF **COMMERCE AND** TECHNOLOGY SENIOR LECTURER A IN CHEMISTRY

Salary on Scale: - £12,357 (Bar) - £14,019 £11.112 required in the Department of Chemistry to promote the research and consultancy interests of the Department and a knowledge of instrumental methods of analysis and the computer control of such instruments would be of particular interest. In addition, the Senior Lecturer would be expected to share the administrative load of the Department and take part in the further development of the BSc Applied Chemistry Course.

Applicants should possess an Honours Degree and/or equivalent professional qualifications, together with a Higher Research Degree and must have substantial relevant research and teaching experience. Recent Industrial experience would be an added advantage.

Application forms and further particulars from: The Administrative Officer (Personnel), Napier College of Commerce and Tech-nology, Colinton Road, Edinburgh EH10 5DT. Closing date: 28th August 1981. (9206)A

UNIVERSITY COLLEGE LONDON

Holmbury St Mary Dorking, Surrey DEPARTMENT OF PHYSICS AND ASTRONOMY

MULLARD SPACE SCIENCE LABORATORY

Three postdoctoral research assistantships financed by the Science and Engineering Research Council and commencing on or after 1 October 1981 are available to space scientists to participate either in the development of imaging detectors for use at X-ray and optical wavelengths, or in a programme of research into the physics of plasmas near the Earth, including the analysis of data from the ESA GEOS spacecraft and the preparation of instruments for the Giotto Comet Halley Flyby and Ampte spacecraft. Commencing salary in the range £6,070 — £7,700 plus USS membership.

Application, with curriculum vitae and the names of two referees, should be made to Professor R L F Boyd CBE, FRS, at the above address.

(9190)A

RESEARCH ASSOCIATE \$16,000

Effective immediately PhD in biochemistry or molecular biology. Experience necessary in area of molecular biology, particularly in recombinant DNA work. Project involves carcinogengenome interactions. Send curriculum vitae and three letters of reference to: Dr. Edward Bresnick, Department of Biochemistry, University of Vermont, Burlington, Vermont (NW787)A

UNIVERSITY OF **BIRMINGHAM**

DEPARTMENT OF BIOCHEMISTRY Applications are invited for a post of

RESEARCH ASSOCIATE

for one year (but may be extended) to ioin a group working on characterisation of muscle protein and muscle nerve interaction. The post involves producing and characterising monoclonal antibodies to myofibrillar proteins and is supported by a grant from the Muscular Dystrophy Group of Great Britain to Professor S V Perry. Research experience in protein chemistry and acquaintance with tissue culture techniques will be an advantage.

Salary within the range £5,285 -£6,070 depending on age, qualifications and experience.

Applications (2 copies) naming 2 referees should be sent by 31st August to Miss J Nelson, Senate Registry, University of Birmingham, PO Box 363, Birmingham B15 2TT, from whom further particulars may be obtained. (9220)A

RESEARCH TECHNICIAN

Position available immediately Applicants should have several years experience in recombinant DNA technology and electron microscopy of nucleic acids. This is a grant sponsored position.

Applications should be sent to: Dr R G Deeley, Department of Biochemistry, Queens University, c/o General Delivery, Watertown, New York 13601, (613) 547-2843.

(NW775)A

SOUTH AFRICAN INSTITUTE FOR MEDICAL RESEARCH PATHOLOGISTS/SCIENCE **GRADUATES**

Applications are invited for posts in Histopathology, Microbiology, Haematology, Clinical Biochemistry, Immunology, Tropical Pathology and Human Genetics. Some of the vacancies are within the School of Pathology, and these are joint posts on the establishment of the Institute and the University of the Witwatersrand. Others are research posts in special fields.

In addition to a competitive salary, the following fringe benefits apply, na rollowing iringe benefits apply, namely, staff pension fund, subsidised medical aid scheme, annual service bonus (13th cheque), 30 days' annual leave and housing bond allowance, where applicable.

A member of the Institute staff will interview applicants in London in the latter part of September or early October. All applications including detailed curriculum vitae should reach the undermentioned by 31 August 1981, in order that an interview may be arranged.

Head: Personnel Services, SAIMR, PO Box 1038, Johannesburg, Republic of South Africa. Telephone: 011-725-0511.

. (W387)A

RECOMBINANT DNA TECHNOLOGIST

Technicians with BA or MS with experience in:

- 1. Bacterial culture and phage growth.
- 2. Nucleic acid isolation and purification.
- Gel electrophoresis, radioactive labelling and hybridization of nucleic acids.
- 4. Molecular cloning (cDNA and/or genomic DNA cloning).

Send Résumé to:

Applied Molecular Genetics, Inc. 1892 Oak Terrace Lane, Newbury Park, CA 91320, (805) 499-3617.

Equal Opportunity Employer.

(NW777)A

UNIVERSITY OF OTAGO Dunedin, New Zealand LECTURESHIP (SCIENCE) IN ORAL BIOLOGY

Applications are invited for appointment to a Lectureship (Science) in the Department of Oral Biology in the Faculty of Dentistry. The successful applicant will have interests and experience appropriate for research and teaching in oral microbiology and his/her principal purpose is the development of collaborative research with clinical staff in the School of Dentistry. In addition, some teaching at undergraduate and postgraduate levels is expected.

Salary: NZ\$19,140 — NZ\$23,520 per annum.

Further particulars are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar, PO Box 56, Dunedin, New Zealand.

Applications close on 30 September 1981. (9218)A

HARVARD SCHOOL OF PUBLIC HEALTH

DEPARTMENT OF BIOSTATISTICS PROFESSOR

Applicants from the fields of Biostatistics, Applied Mathematics or Biomedical Computing are invited to apply. Candidates should be outstanding scholars of international reputation who have made distinguished contributions to be biomedical sciences. The individual selected for this tenured position is expected to initiate and lead a significant research program and participate in the teaching programs of the department.

Send a curriculum vitae, statement of current and future interests and the names of five individuals who would be willing to respond to a request for evaluation to: Professor Donald F Hornig, Harvard School of Public Health, 665 Huntington Avenue, Bldg. 1, Room 1308, Boston, MA 02115, USA.

Harvard University is an Equal Opportunity Employer with an Affirmative Action Program. (NW781)A

UNIVERSITY OF EDINBURGH DEPARTMENT OF BOTANY POST-DOCTORAL RESEARCH FELLOW IN BIOTECHNOLOGY

Applications are invited from Botanists, Biochemists or Microbiologists of post-doctoral status to join a group led by Professor M M Yeoman investigating the synthetic potential of cultured plant cells. This project is funded jointly by Albright and Wilson Ltd and NRDC.

The appointment will be for three years and the initial placement will be at the third or fourth points of range 1A (£6,880 and £7,290) plus superannuation.

Applications, including a curriculum vitae and the names of two referees, should be sent by September 11th to the Secretary, University of Edinburgh, Old College, Edinburgh. Further Particulars may be obtained from Professor M M Yeoman at the Department of Botany. Please quote reference 5040. (9236)A

Recombinant DNA Technology

Armos Corporation

due to expansion of its laboratories, is seeking additional PhD's familiar with:

- * Nucleic Acids Synthesis
- * Expression of Polypeptides in Bacteria or Yeast
- * Virology
- * Immunology
- * Protein Chemistry.

Qualified candidates will play an important role in the growth of the firm while doing research in this exciting field.

ARMOS offers an outstanding salary and benefits package, plus an attractive equity participation program. Female and minority applicants are encouraged to apply.

Please send curriculum vitae, reprints of pertinent publications, and letters of recommendation to ARMOS CORPORATION, 180 Kimball Way, South San Francisco, California 94080.

THE INTERNATIONAL CENTER FOR AGRICULTURAL RESEARCH IN THE DRY AREAS (ICARDA)

has a vacancy for the post of

LIBRARIAN

at its Research Station in Aleppo, Syria. Starting date: January 1, 1982. Qualifications and experience required: MSc or PhD degree in Library Science; fluent English and Arabic; working knowledge of agriculture; working experience in the Arab World.

Applicants should send their c.v. and write for further details to: The Personnel Officer, ICARDA, PO Box 5466, Aleppo, Syria. (W384)A

STANFORD UNIVERSITY California

Applications are invited for an opening at the

ASSISTANT PROFESSOR level in the newly-formed Program in

level in the newly-formed Program in the History of Science.

Candidates should have demonstrated ability in the area of 19th and 20th century physical science.

Curriculum vitae and the names of at least two referees should be sent before November 15, 1981 to: Professor Eric Hutchinson, Academic Secretary, Stanford University, CA 94305.

Stanford University is an equal opportunity employer. (NW762)A

ROYAL MILITARY COLLEGE OF SCIENCE Shrivenham, Swindon, Wilts

DEPARTMENT OF CHEMISTRY AND METALLURGY MAGNETIC CERAMICS

Applications are invited for the post of Research Scientist/ Higher Research Scientist to study the preparation of a range of ferrimagnetic ceramics, and to measure their permeabilities at microwave frequencies. The work will also involve some electron microscopy, X-ray diffraction and computer programming, but advice on these facilities is available if required. A suitable candidate may be able to register for a higher degree.

Applicants must possess a good degree in Ceramics, Materials Science, Physics or Chemistry, or an equivalent qualification, and for the higher post at least two years relevant post-graduate experience is required. Some experience with electrical measurements would be an advantage, but is not essential.

The appointment will be for a 3 year period in the grade of Research Scientist (£4,809 — £6,480) or Higher Research Scientist (£6,075 — £7,999) (salary scales currently under review) depending on qualifications and experience.

Application forms may be obtained from the Civilian Admin Office, Royal Military College of Science, Shrivenham, Swindon, Wilts SN6 8LA; telephone 0793-782551 Ext 421, and further information from Dr. G. B. Perter Ext 356. Please quote reference HQ 120/1/38 in all correspondence. Closing date for applications 20th August 1981. (9181)A

BRIGHTON POLYTECHNIC

DEPARTMENT OF CIVIL ENGINEERING

RESEARCH ASSISTANT

£4,386 -- £5,034

Applications are invited from graduates with good academic qualifications.

The research programme will involve the design of new rock pillars and stability of existing pillars in relation to new methods of working in the Brightling Gypsum Mines.

The successful candidate will be registered for an MPhil/PhD of the CNAA.

Application form and further details from the Deputy Head of Personnel, Brighton Polytechnic, Moulsecoomb, Brighton BN2 4AT. Telephone Brighton 693655 Ext 2537. Closing date 14 August 1981. (9191)A

ROYAL COLLEGE OF SURGEONS OF ENGLAND RESEARCH FELLOW

A vacancy exists for a scientist to join team investigating the microbiological aspects of dental caries at the College's research establishment in Downe, near Orpington, Kent. Much of the work is concerned with the biochemical and immunochemical characterisation of Streptococous mutans, in order to understand the working of an anticaries vaccine. A wide range of bacteriological, biochemical and immunological techniques is in use and the position would suit a recent PhD or good honours graduate, although it will not be possible to enroll for a higher degree.

The initial appointment will be for 3 years. Salary on the University of London Research and Analogous Staff scale IB (£6,252 to £8,667) according to experience.

Please apply to the Personnel Officer, Royal College of Surgeons of England, 35-43 Lincoln's Inc. Fields, London WC2A 3PN

(9197)A

-WANTED-**MOLECULAR BIOLOGIST**

to carry out study of immunoglobulin gene arrangement in human leukemias and lymphomas. Background in relevant techniques (Southern blotting, nicktranslation, etc.) required; some experience in immunology helpful, but not necessary. Appointment is at the research associate level; exceptionally qualified individuals will be considered at the Assistant Member (Professor) level. Position available immediately.

Send a curriculum vitae and the names of three references to: Dr. G. R. Kitchingman, Division of Virology, St. Jude Children's Research Hospital, Memphis, TN. 38101. (NW790)A

NATIONAL BIOLOGICAL STANDARDS BOARD **PHARMACOLOGIST**

There is an immediate vacancy for a post-doctoral pharmacologist in the Division of Hormones. The work currently involves research on the mechanism of action and methods of detection of pyrogens. and in the characterization of small pharmacologically-active peptides such as gut peptides.

Applicants should have a postdoctoral degree in pharmacology or physiology and have had experience of laboratory pharmacology or physiology and have had experience of laboratory pharmacology research.

The salary payable is in accordance with qualifications, age and experience on the M.R.C. Grade II (£7,037 p.a. - £10,717 p.a. inclusive).

For further details and an application form please contact the Personnel Officer, NIBSC Holly Hill, Hampstead, London NW3 6RB. Tel: 01-435 2232. Please quote ref. no (HO/049. Closing date 28th August 1981. (9209) A

POSTDOCTORAL position available immediately for studies into the biochemistry of calcium transport during avian egg shell mineralization and its regulation by Vitamin D. A strong background in biochemistry required; experience in membrane transport and/or subcellular fractionation preferred. Salary starting at \$15,800 plus fringe benefits. Send résumé and letters of recommenda-tion to: Dr William A. Coty, Department of Biological Chemistry UCLA School of Medicine, Los Angeles, CA 90024. UCLA is an Equal Opportunity/Affirmative Action Employer. (NW791)A

McGILL UNIVERSITY DEPARTMENT OF MICROBIOLOGY MACDONALD CAMPUS

RESEARCH ASSOCIATE

Applications are invited for a research associate to study aspects of the molecular biology of membrane transport. The study will involve cloning of genes for transport proteins, in vitro synthesis transport proteins and DNA sequencing.

Applicants should hold a PhD degree in Molecular Biology or in Biochemistry or Microbiology and have had previous laboratory experience, preferably at the postdoctoral level in the molecular biological techniques required for this study

Salary \$22,000 per annum.

Please apply in writing giving full curriculum vitae and the names and addresses of two referees to: Dr R A MacLeod, Department of Microbiology, Macdonald Campus, McGill University, Ste Anne de Bellevue, Quebec, Canada H9X 1CO

(NW782)A

FELLOWSHIPS

UNIVERSITY OF LEICESTER SCHOOL OF BIOLOGICAL

SCIENCES

ICI/UNIVERSITY JOINT **LABORATORY** Applications are invited for a POST-DOCTORAL **FELLOWSHIP**

in a group studying the molecular genetics of methylotrophic bacteria.

The post provides an opportunity to use modern bacterial genetics and recombinant DNA techniques to study chromosomal organisation in an industrial micro-organism. Applicants should have postgraduate experience in a relevant discipline, but experience in molecular cloning is not essential.

The salary will be in the research and analogous scale £6,070 — £10,575 and the appointment will initially be for two years.

Applicants should send curriculum vitae and the names and addresses of two referees to Professor W J Brammar, Department of Biochemistry, University of Leicester, Leicester LE1 7RH, from whom further details can be obtained.

UNIVERSITY COLLEGE **DUBLIN**

DEPARTMENT OF CHEMISTRY

Applications are invited for a POST-DOCTORAL **FELLOWSHIP IN** PHYSICAL CHEMISTRY

for a theoretical investigation of transport processes in the corrosion of metals. The appointment which is supported by the National Board for Science and Technology of Ireland, will commence as soon as possible after September 1st, 1981. It will be initially for one year with a possibility of renewal for a further two years. Salary will be in the range IR£5,370 - IR£6,234.

Applications accompanied by a Curriculum Vitae and the names of two Referees should be sent to: Dr Corish, Department of Chemistry, University College, Belfield, Dublin (9199)E 4. Ireland.

LA TROBE UNIVERSITY Melbourne, Australia SCHOOL OF AGRICULTURE

RESEARCH FELLOWSHIP IN IMMUNOLOGY

The Wool Research Trust Fund is funding a postdoctoral Fellow to work on the development of assays for sheep IgE and their application to an understanding of natural resistance to common parasites.

Salary: \$A17,083 — \$A26,037.

Further information and application forms are available from the Association of Commonwealth Universities (Appts), 36 C Square, London WC1H 0PF. 36 Gordon

Applications close on 14th August (9182)E

ROYAL NATIONAL HOSPITAL FOR RHEUMATIC DISEASES AND UNIVERSITY OF BATH SIDNEY ROBINSON RESEARCH FELLOWSHIP

Applications are invited for th above Fellowship tenable for two years from October 1981. successful applicant will join at active research team working on the biochemical and functiona characterisation of lymphocyte subpopulation in-patients with rheumatic diseases. Candidate should have a PhD in immunolog; and should preferably have some experience in lymphocyte culture The appointment will be made on the University Research Officer/Medica Registrar scale as appropriate.

Send SAE for application form and descriptive leaflet to the Hospita Administrator, Royal Nationa Hospital for Rheumatic Diseases Upper Borough Walls, Bath BA1

Closing date 8th September 1981. (9189)E

OUEEN MARY COLLEGE University of London CHEMISTRY DEPARTMENT

Applications are invited for a

POSTDOCTORAL RESEARCH FELLOWSHIP

for ESR studies on food constituents in exploratory work supervised jointly by Professor R Bonnett and Dr K D Sales. Appointment is for 1 year from 1 October 1981. Salary in rage £7,037 — £8.257.

Please apply by letter, including c.v. and names of 2 referees, to The Secretary, (N) Queen Mary College, Mile End Road, London E1 4NS (9207)F

UNIVERSITY OF KENT AT CANTERBURY

ELECTRONICS LABORATORY

RESEARCH FELLOWSHIP

Applications are invited for the post Research Fellow to work on a DHSS-supported project to study the application of pattern recognition techniques to the design of a microprocessor-based speech therapy aid. Applicants should have a good Honours degree in electronics or computer engineering and should preferably hold a PhD degree in an appropriate area. The appointment is for two years and the salary will be in the range £6,070 - £7,290 on the Grade 1A scale.

Application forms and further particulars may be obtained from the Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH. The closing date for applications is 25 August 1981. Please quote ref. A21/81/N. (9208)E

"QUEEN'S FELLOWSHIPS IN MARINE SCIENCE"

To commemorate the Royal Visit to Australia in 1970 the Australian Government established the Queen's Fellowships Scheme. Under this Scheme up to five fellowships may be awarded each year for full-time research by young scientists of exceptional promise and proven capacity for original work. These awards are tenable at an Australian university or approved research institution normally for two years. Tenure of a Fellowship is expected to commence within nine months of the announcement of the award.

QUALIFICATIONS: Queen's Fellows should have a Ph.D., or equivalent qualifications, or equivalent research or professional experience in a

discipline applicable in marine science or coastal engineering.

SALARY: \$21509 (Australian) per annum – increased to \$23107 at age of 28 years (at present under review).

TRAVEL EXPENSES: Necessary travel expenses are payable.

APPLICATIONS: Persons interested in applying for the above fellowships should obtain application forms from: The Minister (Scientific), Australia House, The Strand, London WC2B4LA. The next round of awards will be announced in January 1982. Applications close in Canberra on 11 September 1981.

(9231)E

UNIVERSITY OF EXETER STRUCTURAL STUDIES OF LIQUID CRYSTALS

Applications are invited for an SERC Postdoctoral Research Fellowship to work with Professor A J Leadbetter on X-ray diffraction studies of smectic liquid crystals. A new position-sensitive X-ray detection system will be used to study novel structures and phase transitions in these systems and some neutron scattering work using the facilities at ILL Grenoble will also be involved. Applicants may be chemists or physicists and some experience of X-ray or neutron diffraction and computing would be an advantage, though not essential.

The period of the Fellowship is 1 October 1981 until 31 July 1983 with starting salary up to £6,880 per annum depending on age and experience.

Applications should be sent as soon as possible to Professor A J Leadbetter, Department of Chemistry, Stocker Road, Exeter EX44QD. (9200)E

KING'S COLLEGE Cambridge RESEARCH FELLOWSHIPS IN CHEMISTRY

Applications are invited for Junior Research Fellowships in Chemistry to commence on 1 October 1982. The normal tenure is four years, ending 30 September 1986. Arrangements have been made for successful candidates to work in either the Department of Organic and Inorganic Chemistry or the Department of Physical Chemistry.

Men and women graduates of any university are eligible, provided they have not completed more than about three years of post-graduate research by October 1981. Stipends range from about £5,200 to about £6,900 a year and an unmarried Fellow is provided with accommodation in College if he or she wishes.

Applications will need to be made by 31 October 1981. Write for further details to the Provost, King's College, Cambridge CB2 1ST.

(9237)E

EDUCATION COMMITTEE
Mid-Kent College of Higher and
Further Education
DEPARTMENT OF SCIENCE

Postdoctoral Research Fellowship

A vacancy exists in the Department for a Postdoctoral Fellow to undertake research with Dr. M. A. Malati in the field of photocatalysed heterogeneous reactions.

The post is available for two years, with a starting salary within the NJC (B) Scale (£6,462 — £8,820).

Applications, accompanied in each case by a curriculum vitae and the names of two referees should be sent to:

The Principal,
Mid-Kent College of Higher and Further Education,
Horsted, Chatham, Kent ME5 9UQ.

QUEEN ELIZABETH II FELLOWSHIPS Physical & Biological Sciences

To commemorate the Royal Visit to Australia in 1963 the Australian Government established the Queen Elizabeth II Fellowships Scheme Under this scheme up to ten fellowships may be awarded each year for full-time research by young scientists of exceptional promise and proven capacity for original work. These are post-doctoral awards tenable in an Australian university or approved research institution normally for two years. Tenure of a Fellowship is expected to commence within nine months of the announcement of the award.

QUALIFICATIONS: Queen Elizabeth II Fellows must be either Australian or United Kingdom citizens. They should have a Ph.D., or equivalent qualifications, in one of the physical or biological sciences (which are deemed to include mathematics and the scientific aspects of statistics, engineering, metallurgy, agriculture and medicine). Awards will, in general, be restricted to applicants who are not more than 30 years of age on the date when applications close. Applications will also be considered from those candidates for the Ph.D. degree who have submitted their thesis for examination.

SALARY: \$21509 (Australian) per annum – increased to \$23107 per annum at age 28 years (at present under review).

TRAVEL EXPENSES: Necessary travel expenses are payable.

APPLICATIONS: Persons interested in applying for the above fellowships should obtain application forms and a statement of the conditions of award from: The Minister (Scientific), Australia House, The Strand, London WC2B 4LA. The next round of awards will be announced in December 1981. Applications close in Canberra on 28 August 1981.

(9232)E

STUDENTSHIPS

QUEEN ELIZABETH COLLEGE

Kensington (University of London)

BIOLOGY DEPARTMENT

SRC/CASE STUDENTSHIP CYTODIFFERENTIATION OF CALLUSES IN PRUNUS & MALUS

Applications are invited from graduates in Biology or Botany with a minimum of an Upper Second Class Honours degree for the above project in collaboration with East Malling Research Station, Kent. A knowledge of tissue culture and histochemistry will be an advantage, but not essential.

Applications to Professor P B Gahan, Biology Department, Queen Elizabeth College, Campden Hill Road, Kensington, London W8 7AH, with a curriculum vitae and the names and-addresses of 2 academic referees. The successful applicant will register for a higher degree of the University of London. (9215)F

THE UNIVERSITY OF MANCHESTER

DEPARTMENT OF OBSTETRICS
AND GYNAECOLOGY

Applications are invited for an

SRC/CASE STUDENTSHIP

in collaboration with Dr M Dukes, Biosciences I, ICI Limited, Macclesfield, Cheshire on a project involving the action of Novel Polymer Disrupting Compounds on Human Cervical Mucus Glycoprotein and their effect on the glycoprotein biochemistry and sperm penetration. Candidates should have (or expect to obtain) a First or Upper Second Class degree in Bio-Chemistry or a related subject.

Applications including Curriculum Vitae and names and addresses of two referees should be sent as soon as possible to Dr E Chantler, Department of Obstetrics and Gynaecology, Research and Teaching Block, Withington Hospital, Nell Lane, Manchester 20. (9196)F

UNIVERSITY OF EDINBURGH

DEPARTMENTS OF BOTANY AND GENETICS

SRC CASE STUDENTSHIP

Applications are invited from candidates with a first or upper second class honours degree in Botany or Microbiology for a three year CASE studentship to study the genetics of *Erwinia carotovora* in relation to its pathogenicity to potato.

The research will be carried out at the University of Edinburgh (under the supervision of Dr R O D Dixon, Department of Botany and Dr E C R Reeve, Department of Genetics) and at the Scottish Crop Research Institute, Dundee (under the supervision of Dr M C M Perombelon).

Applications, including curriculum vitae and names of two referees should be sent as soon as possible to Dr R O D Dixon, Department of Botany, University of Edinburgh, The King's Buildings, Mayfield Road, Edinburgh EH9 3JH (031-667 1081) from whom further information may be obtained.

(9195)F

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF PHARMACOLOGY POSTGRADUATE STUDENTSHIP

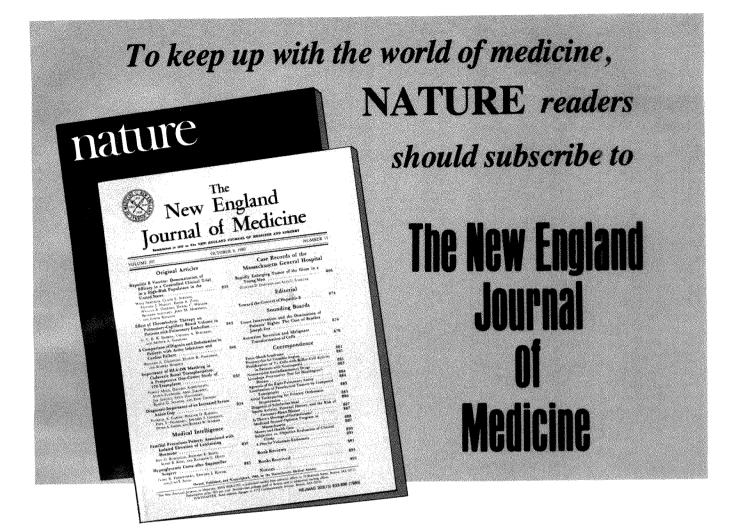

Applications are invited from UK graduates with a 1st or II(i) Honours Degree in Pharmacology or related discipline, for 3 year postgraduate scholarship concerned with the pharmacology of cerebral vasospasm.

Applications, including a curriculum vitae and the names of 2 referees, should be sent as soon as possible to: Professor P B Bradley, Department of Pharmacology, The Medical School, Birmingham B15 2TJ. (9194)F

CLASSIFICATION OF GREENLAND MICROFOSSILS

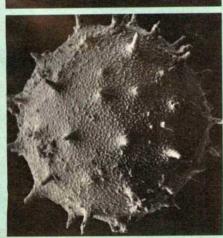

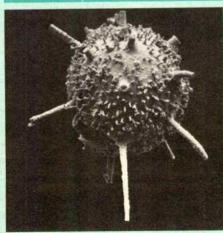

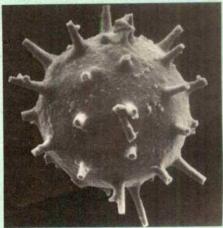

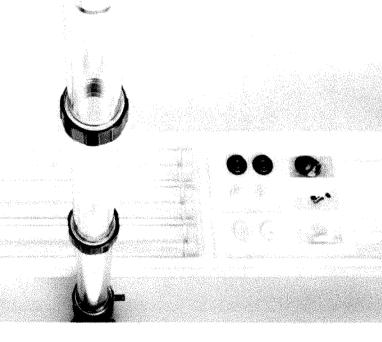

The Complete Clumn

- Everything you need comes in a convenient do-it-yourself kit
- Applicable for any bed height from 5 to 95 cm
- The same low cost for both \emptyset 16 and 26 mm I.D.

- Assembles in less than 5 minutes without any extra tools
- Packing cylinder and reservoir available as accessory
- Sample applicator included

Head office: LKB-Produkter AB Box 305 S-16126 Bromma, Sweden Tel. 08-980040, telex 10492 Main US sales office: LKB Instruments, Inc. 12221 Parklawn Drive Rockville, MD 20852 Tel. 301-881 25 10, telex 230 89 682

INTRODUCING

BRL Chromatography Columns

- Versatile, Top Quality Columns at Reasonable Prices for ion exchange, gel filtration, affinity and adsorbent chromatography.
- Wide Range of Column Sizes—from 0.9 x 15 cm (9.4 ml bed volume) to 15 x 100 cm (17,700 ml bed volume).
- Borosilicate Glass and Polypropylene Construction for aqueous systems. Teflon end plates and adjustable plungers are available for organic solvent systems.
- Adjustable Plungers—can be added to reduce extra-bed mixing or for ascending flow systems. Can be installed from either or both ends of the column.
- Moderate Pressures—(20-125 p.s.i. depending upon column size) can be used to increase or stabilize flow rates.
- Columns Dismantle Completely—for easy cleanup.
- Side Vent Port—on top end plate for bleeding air or sample addition.
- End Plates Adapt to Commercial Tubing—no special tubing or flaring tool required.
- Unique Non-Clogging Bed Support—consisting of a thin 10μ membrane suspended over a woven grid minimizes dead volume.

And Accessories

- Packing Reservoirs
 Water Jackets
- Column Extenders
 ◆ Adjustable Plungers
 ◆ Valves and Tubing

How Britain runs its Science

This highly successful wallchart, which first appeared in 1975, has now been completely revised and updated.

The 2×3 ft guide offers a comprehensive survey of the administration of British science. It provides a full account of the funding of science in Britain, giving details of money spent by government, research councils, industry and universities.

Designed as a fold-out sheet, it can be carried easily to meetings or hung as a wall poster for permanent reference. The new 1981 edition is available at £3.50 or \$7.95 by sending your cheque to either Nature's London or New York offices.

In the UK and elsewhere: Nature, 4 Little Essex Street, London WC2R 3LF, England.
